## Best-First Search

Search procedures differ in the way they determine the next node to expand.

- Uninformed Search: Rigid procedure with no knowledge of the cost of a given node to the goal.
  - **Informed Search:** Knowledge of the worth of expanding a node n is given in the form of an *evaluation function* f(n), which assigns a real number to each node. Mostly, f(n) includes as a component a *heuristic function* h(n), which estimates the costs of the cheapest path from n to the goal.

Best-First Search: Informed search procedure that expands the node with the "best" *f*-value first.

#### Contents

## General Algorithm

function TREE-SEARCH(problem) returns a solution, or failure initialize the frontier using the initial state of *problem* loop do if the frontier is empty then return failure choose a leaf node and remove it from the frontier if the node contains a goal state then return the corresponding solution

expand the chosen node, adding the resulting nodes to the frontier

Best-first search is an instance of the general TREE-SEARCH algorithm in which frontier is a priority queue ordered by an evaluation function f.

When f is always correct, we do not need to search!

#### **Greedy Search**

A possible way to judge the "worth" of a node is to estimate its path-costs to the goal.

h(n) = estimated path-costs from n to the goal

The only real restriction is that h(n) = 0 if n is a goal.

A best-first search using h(n) as the evaluation function, i.e., f(n) = h(n)is called a greedy search.

Example: route-finding problem:

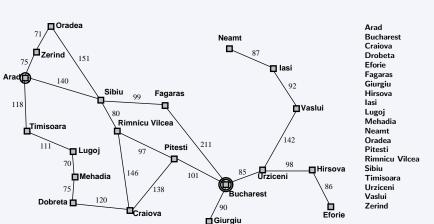

h(n) =straight-line distance from n to the goal

#### Heuristics

The evaluation function h in greedy searches is also called a *heuristic* function or simply a *heuristic*.

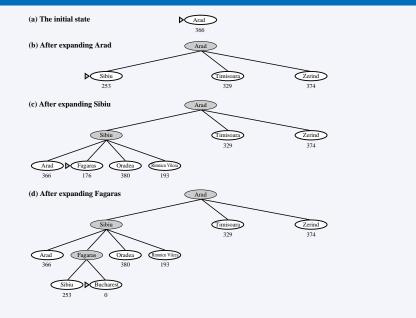

- The word *heuristic* is derived from the Greek word  $\varepsilon v \rho \iota \sigma \kappa \varepsilon \iota \nu$  (note also:  $\varepsilon v \rho \eta \kappa \alpha!$ )
- The mathematician Polya introduced the word in the context of problem solving techniques.
- In AI it has two meanings:
  - Heuristics are fast but in certain situations incomplete methods for problem-solving [Newell, Shaw, Simon 1963] (The greedy search is actually generally incomplete).
  - Heuristics are methods that improve the search in the average-case.
- $\rightarrow$  In all cases, the heuristic is *problem-specific* and *focuses* the search!

# Greedy Search from Arad to Bucharest

#### Greedy Search - Properties

- a good heuristic might reduce search time drastically
- non-optimal
- incomplete
- graph-search version is complete only in finite spaces

#### Can we do better?

(University of Freiburg)

#### A\*: Minimization of the Estimated Path Costs

 $\mathbf{A}^*$  combines the greedy search with the uniform-search strategy: Always expand node with lowest f(n) first, where

g(n) = actual cost from the initial state to n.

h(n) =estimated cost from n to the next goal.

f(n) = g(n) + h(n),

the estimated cost of the cheapest solution through n.

Let  $h^*(n)$  be the actual cost of the optimal path from n to the next goal. h is *admissible* if the following holds for all n:

$$h(n) \le h^*(n)$$

We require that for  $A^*$ , h is admissible (example: straight-line distance is admissible).

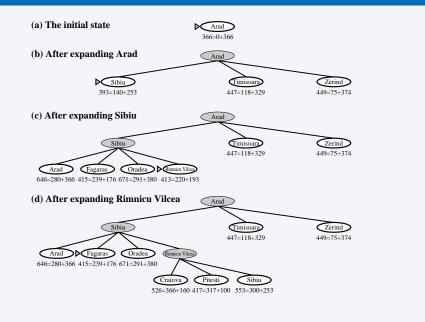

In other words, h is an *optimistic* estimate of the costs that actually occur.

# A\* Search from Arad to Bucharest

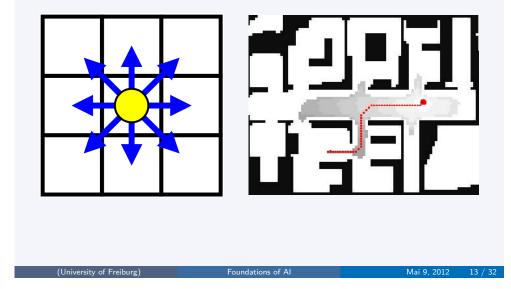

# A\* Search Example

#### A\* Search from Arad to Bucharest

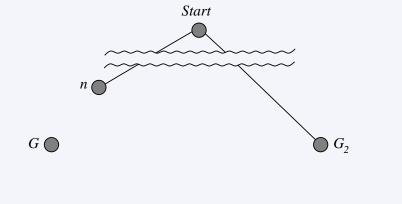

# Optimality of A\*

Claim: The first solution found has the minimum path cost.

**Proof:** Suppose there exists a goal node G with optimal path cost  $f^*$ , but  $A^*$  has found another node  $G_2$  with  $g(G_2) > f^*$ .

## Optimality of A\*

Let n be a node on the path from the start to  ${\cal G}$  that has not yet been expanded. Since h is admissible, we have

$$f(n) \le f^*.$$

Since n was not expanded before  $G_2$ , the following must hold:

$$f(G_2) \le f(n)$$

and

$$f(G_2) \le f$$

It follows from 
$$h(G_2) = 0$$
 that

 $g(G_2) \le f^*.$ 

 $\rightarrow$  Contradicts the assumption!

Mai 9, 2012 14 / 32

#### Completeness and Complexity

#### **Completeness:**

If a solution exists, A<sup>\*</sup> will find it provided that (1) every node has a finite number of successor nodes, and (2) there exists a positive constant  $\delta > 0$  such that every step has at least cost  $\delta$ .

 $\rightarrow$  there exists only a finite number of nodes n with  $f(n) \leq f^*$ .

#### **Complexity:**

In general, still exponential in the path length of the solution (space, time)

More refined complexity results depend on the assumptions made, e.g. on the quality of the heuristic function. Example:

In the case in which  $|h^*(n) - h(n)| \le O(\log(h^*(n)))$ , only one goal state exists, and the search graph is a tree, a sub-exponential number of nodes will be expanded [Gaschnig, 1977, Helmert & Roeger, 2008].

Mai 9, 2012 17 /

#### Variants of A\*

A\* in general still suffers from exponential memory growth. Therefore, several refinements have been suggested:

- iterative-deepening A\*, where the f-costs are used to define the cutoff (rather than the depth of the search tree): IDA\*
- Recursive Best First Search (RBFS): introduces a variable *f\_limit* to keep track of the best alternative path available from any ancestor of the current node. If current node exceeds this limit, recursion unwinds back to the alternative path.
- other alternatives (not discussed here) memory-bounded A\* (MA\*), and simplified MA\*, SMA\*.

18	14	Ŵ	15	15	14	Ŵ	16
14	14	13	17	12	14	12	18

## Local Search Methods

- In many problems, it is unimportant how the goal is reached only the goal itself matters (8-queens problem, VLSI Layout, TSP).
- If in addition a quality measure for states is given, a **local search** can be used to find solutions.
- operates using a single current node (rather than multiple paths)
- use very little memory
- Idea: Begin with a randomly-chosen configuration and improve on it stepwise  $\rightarrow$  Hill Climbing.
- note: can be used for maximization or minimization respectively (see 8 queens example)

Mai 9, 2012 21 / 3

## Hill Climbing

(University of Freiburg

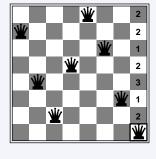

function HILL-CLIMBING(problem) returns a state that is a local maximum

 $\textit{current} \gets \textsf{Make-Node}(\textit{problem}.\textsf{Initial-State})$  loop do

 $\begin{array}{l} \textit{neighbor} \leftarrow \text{a highest-valued successor of } \textit{current} \\ \textbf{if neighbor.VALUE} \leq \textit{current.VALUE then return } \textit{current.STATE} \\ \textit{current} \leftarrow \textit{neighbor} \end{array}$ 

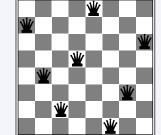

#### Example: 8-Queens Problem (2)

Possible realization of a hill-climbing algorithm: Select a column and move the queen to the square with the fewest conflicts.

(University of Freiburg)

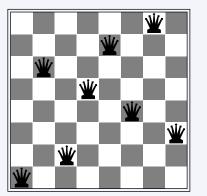

Mai 9, 2012

24 / 32

## Example: 8-Queens Problem (Local Minimum)

Local minimum (h = 1) of the 8-Queens Problem. Every successor has a higher cost.

Foundations of AI

## Problems with Local Search Methods

- Local maxima: The algorithm finds a sub-optimal solution.
- *Plateaus:* Here, the algorithm can only explore at random.
- Ridges: Similar to plateaus.

#### Solutions:

- Start over when no progress is being made.
- $\bullet \ \ ``Inject \ noise'' \ \rightarrow \ random \ walk$

Which strategies (with which parameters) are successful (within a problem class) can usually only empirically be determined.

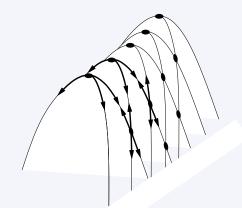

#### (University of Freiburg)

Foundations of AI

Mai 9, 2012 25 / 32

#### Illustration of the ridge problem

The grid of states (dark circles) is superimposed on a ridge rising from left to right, creating a sequence of local maxima, that are not directly connected to each other. From each local maximum, all the available actions point downhill.

Foundations of A

#### Performance figures for the 8-Queens Problem

8 queens has about  $8^8 \approx 17 \ million$  states. Starting from a random initialization, hill-climbing directly finds a solution in about 14% of the cases. Needs in average only 4 steps!

Better algorithm: allow sideways moves (no improvement), but restrict the number of moves (avoid infinite loops!).

E.g.: max. 100 moves: solves 94%, number of steps raises to 21 steps for successful instances and 64 for each failure.

#### (University of Freiburg)

Foundations of AI

#### Genetic Algorithms

Evolution appears to be very successful at finding good solutions.

*Idea:* Similar to evolution, we search for solutions by "crossing", "mutating", and "selecting" successful solutions.

#### Ingredients:

- Coding of a solution into a string of symbols or bit-string
- A fitness function to judge the worth of configurations
- A population of configurations

*Example:* 8-queens problem as a chain of 8 numbers. Fitness is judged by the number of non-attacks. The population consists of a set of arrangements of queens.

## Simulated Annealing

In the simulated annealing algorithm, "noise" is injected systematically: first a lot, then gradually less.

```
\begin{array}{l} \textbf{function SIMULATED-ANNEALING}(problem, schedule) \textbf{ returns a solution state}\\ \textbf{inputs:} problem, a problem\\ schedule, a mapping from time to "temperature"\\ current \leftarrow MAKE-NODE(problem.INITIAL-STATE)\\ \textbf{for } t = 1 \textbf{ to } \infty \textbf{ do}\\ T \leftarrow schedule(t)\\ \textbf{ if } T = 0 \textbf{ then return } current\\ next \leftarrow a randomly selected successor of current\\ \Delta E \leftarrow next.VALUE - current.VALUE\\ \textbf{ if } \Delta E > 0 \textbf{ then } current \leftarrow next\\ \textbf{ else } current \leftarrow next \text{ only with probability } e^{\Delta E/T}\\ \end{array}
```

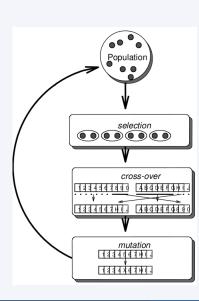

Has been used since the early 80's for VSLI layout and other optimization problems.

```
(University of Freiburg)
```

## Selection, Mutation, and Crossing

Many variations:

how selection will be applied, what type of cross-over operators will be used, etc.

Selection of individuals according to a fitness function and pairing

Calculation of the breaking points and recombination

According to a given probability elements in the string are modified.

Mai 9, 2012

28 / 32

#### Summary

- Heuristics focus the search
- Best-first search expands the node with the highest worth (defined by any measure) first.
- With the minimization of the evaluated costs to the goal *h* we obtain a greedy search.
- The minimization of f(n) = g(n) + h(n) combines uniform and greedy searches. When h(n) is admissible, i.e.,  $h^*$  is never overestimated, we obtain the A<sup>\*</sup> search, which is complete and optimal.
- IDA\* is a combination of the iterative-deepening and A\* searches.
- Local search methods only ever work on one state, attempting to improve it step-wise.
- Genetic algorithms imitate evolution by combining good solutions.
