The SLAM Problem

- SLAM stands for simultaneous localization and mapping
- The task of building a map while estimating the pose of the robot relative to this map

- Why is SLAM hard? Chicken-or-egg problem:
 - A map is needed to localize the robot
 - A pose estimate is needed to build a map

The SLAM Problem

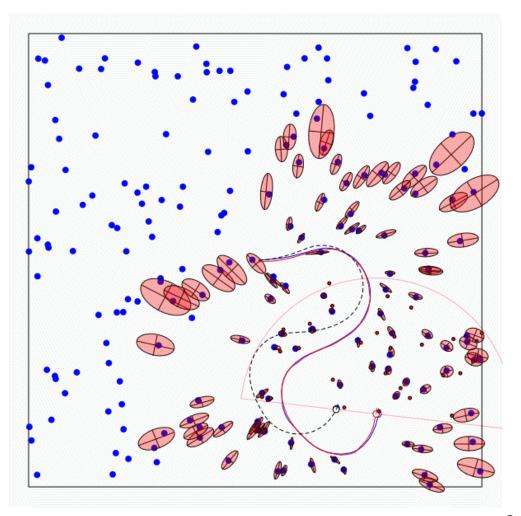

A robot moving though an unknown, static environment

Given:

- The robot's controls
- Observations of nearby features

Estimate:

- Map of features
- Path of the robot

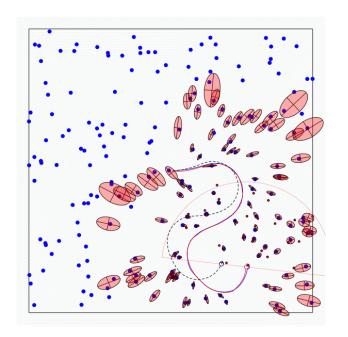

Map Representations

Typical models are:

Feature maps

today

 Grid maps (occupancy of reflection probability maps)

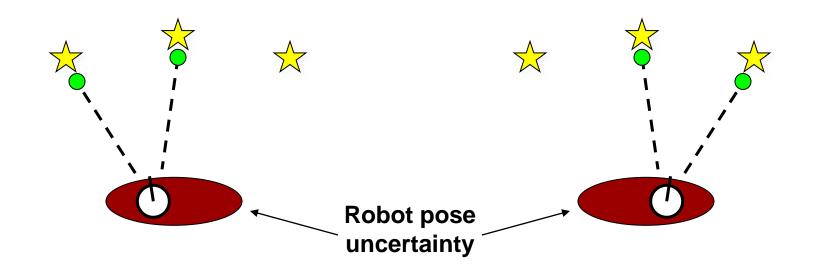

Why is SLAM a Hard Problem?

SLAM: robot path and map are both unknown!

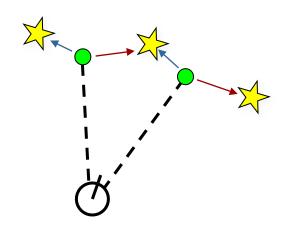

Robot path error correlates errors in the map

Why is SLAM a Hard Problem?

- In the real world, the mapping between observations and landmarks is unknown
- Picking wrong data associations can have catastrophic consequences
- Pose error correlates data associations

Data Association Problem

- A data association is an assignment of observations to landmarks
- In general there are more than $\binom{n}{m}$ (n observations, m landmarks) possible associations
- Also called "assignment problem"

Particle Filters

- Represent belief by random samples
- Estimation of non-Gaussian, nonlinear processes
- Sampling Importance Resampling (SIR) principle
 - Draw the new generation of particles
 - Assign an importance weight to each particle
 - Resampling
- Typical application scenarios are tracking, localization, ...

Localization vs. SLAM

- A particle filter can be used to solve both problems
- Localization: state space $\langle x, y, \theta \rangle$
- SLAM: state space $\langle x, y, \theta, map \rangle$
 - for landmark maps = $\langle I_1, I_2, ..., I_m \rangle$
 - for grid maps = $\langle c_{11}, c_{12}, ..., c_{1n}, c_{21}, ..., c_{nm} \rangle$
- Problem: The number of particles needed to represent a posterior grows exponentially with the dimension of the state space!

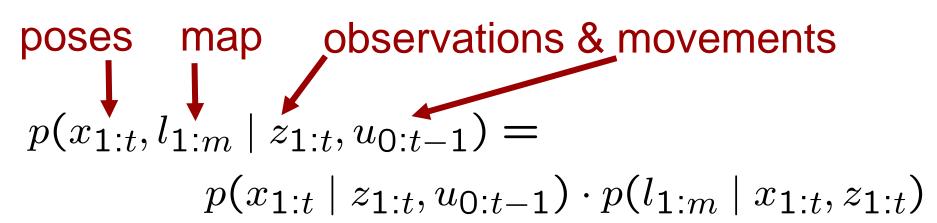

Dependencies

- Is there a dependency between the dimensions of the state space?
- If so, can we use the dependency to solve the problem more efficiently?

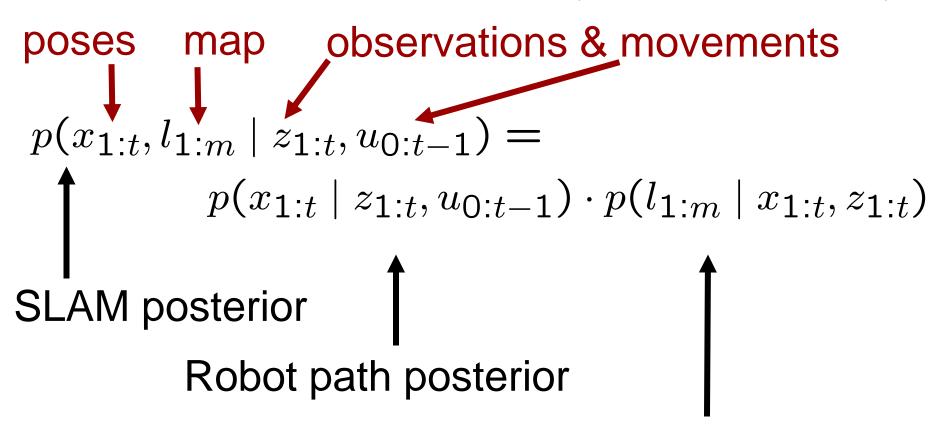

Dependencies

- Is there a dependency between the dimensions of the state space?
- If so, can we use the dependency to solve the problem more efficiently?
- In the SLAM context
 - The map depends on the poses of the robot.
 - We know how to build a map given the position of the sensor is known.

Factored Posterior (Landmarks)

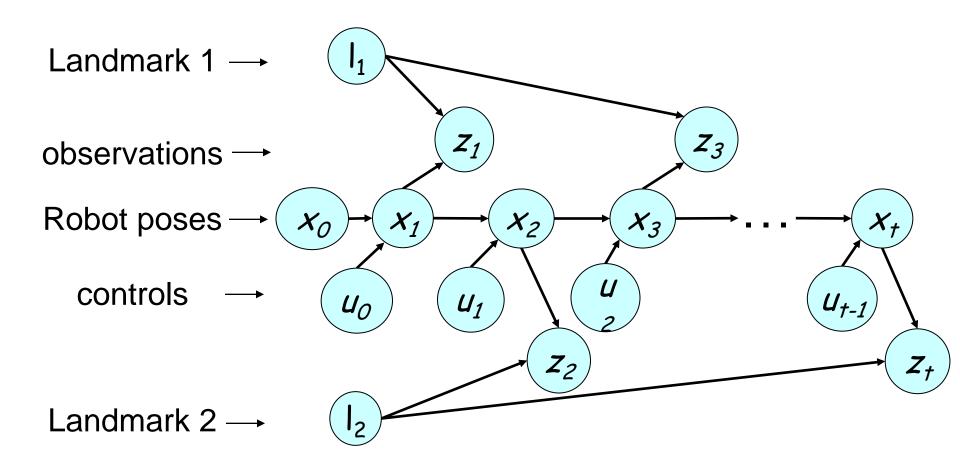

Factored Posterior (Landmarks)

landmark positions

Does this help to solve the problem?

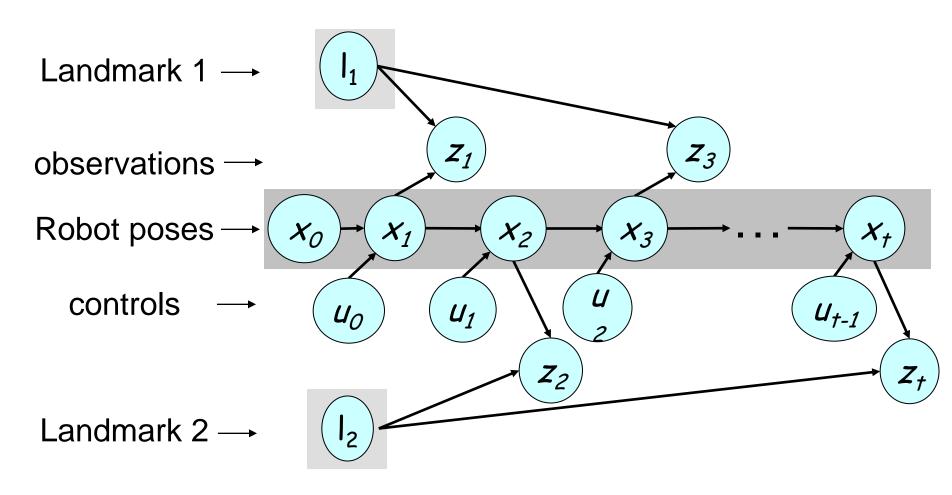

Mapping using Landmarks

Bayes Network and D-Separation (See AI or PGM course)

- X and Y are independent if d-separated by V
- V d-separates X from Y if every undirected path between X and Y is blocked by V
- A path is blocked by V if there is a node W on the graph such that either:
 - W has converging arrows along the path
 (→ W ←) and neither W nor its descendants are
 observed (in V), or
 - W does not have converging arrows along the path (→ W → or ← W →) and W is observed (W ∈ V).

Mapping using Landmarks

Knowledge of the robot's true path renders landmark positions conditionally independent

Factored Posterior

$$p(x_{1:t}, l_{1:m} \mid z_{1:t}, u_{0:t-1})$$

$$= p(x_{1:t} \mid z_{1:t}, u_{0:t-1}) \cdot p(l_{1:m} \mid x_{1:t}, z_{1:t})$$

$$= p(x_{1:t} \mid z_{1:t}, u_{0:t-1}) \cdot \prod_{i=1}^{M} p(l_i \mid x_{1:t}, z_{1:t})$$

Robot path posterior (localization problem)

Conditionally independent landmark positions

Rao-Blackwellization

$$p(x_{1:t}, l_{1:m} \mid z_{1:t}, u_{0:t-1}) =$$

$$p(x_{1:t} \mid z_{1:t}, u_{0:t-1}) \cdot \prod_{i=1}^{M} p(l_i \mid x_{1:t}, z_{1:t})$$

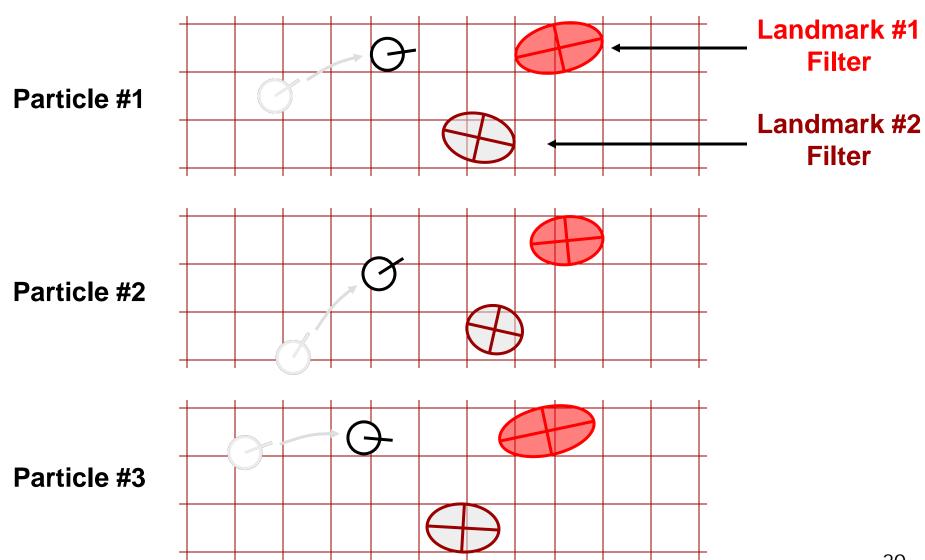

- This factorization is also called Rao-Blackwellization
- Given that the second term can be computed efficiently, particle filtering becomes possible!

FastSLAM

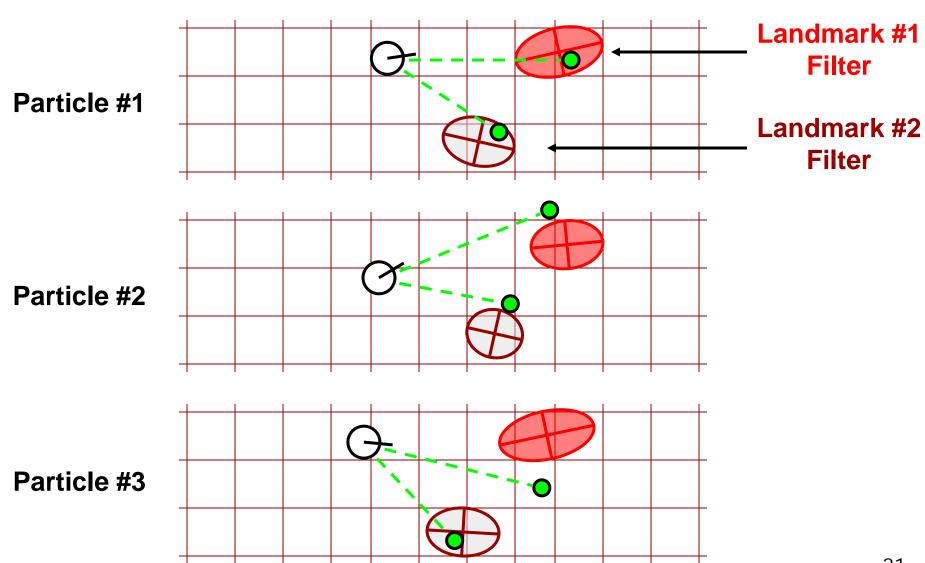

- Rao-Blackwellized particle filtering based on landmarks [Montemerlo et al., 2002]
- Each landmark is represented by a 2x2
 Extended Kalman Filter (EKF)
- Each particle therefore has to maintain M EKFs

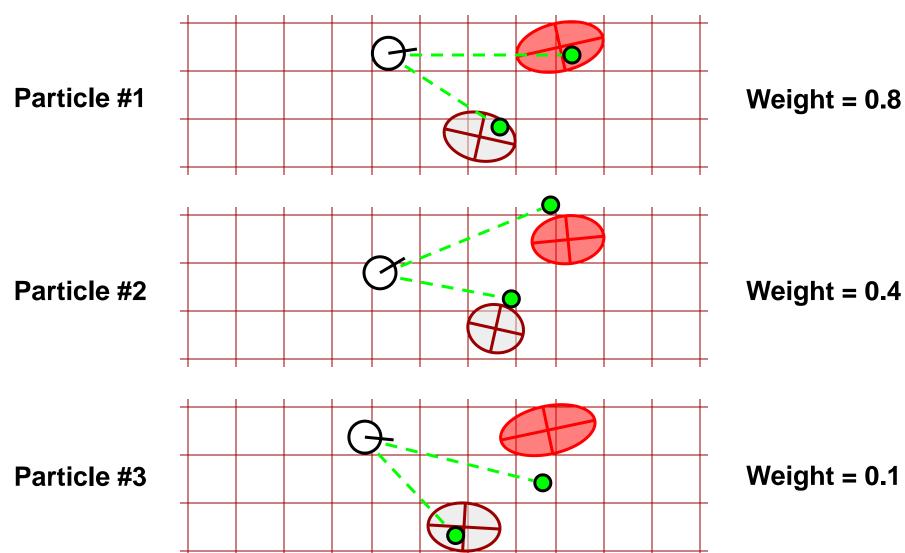

FastSLAM – Action Update

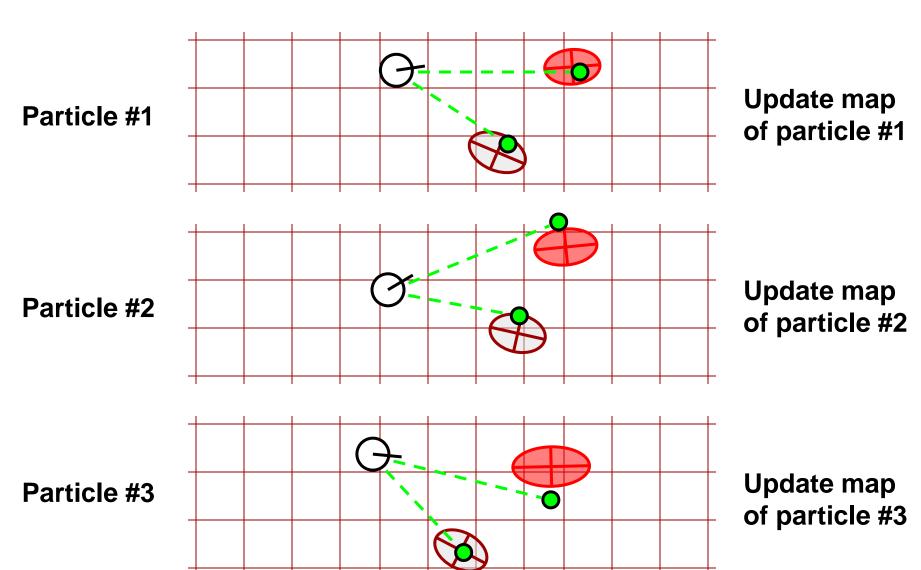

FastSLAM – Sensor Update

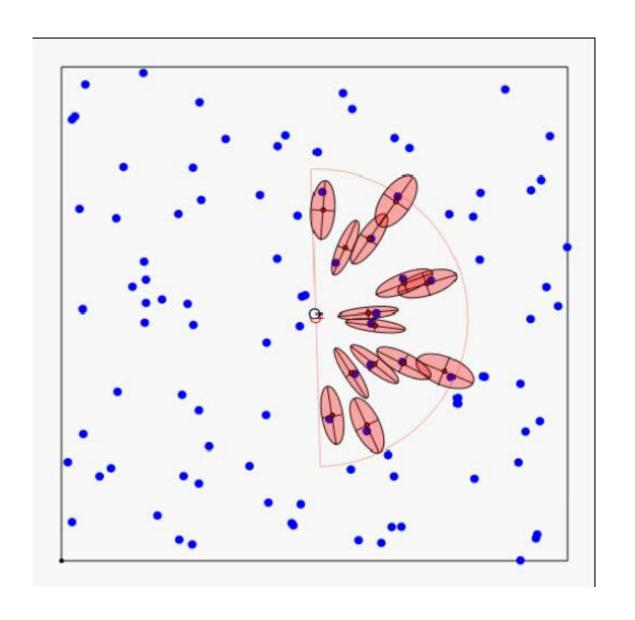

FastSLAM – Sensor Update

FastSLAM – Sensor Update

FastSLAM - Video

FastSLAM Complexity

 Update robot particles based on control u_{t-1} O(N)
Constant time
(per particle)

 Incorporate observation z_t into Kalman filters

O(N•log(M))
Log time (per particle)

Resample particle set

O(N•log(M))
Log time (per particle)

N = **N**umber of particles

M = Number of map features

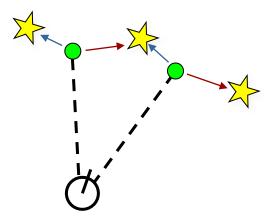

O(N•log(M))

Log time in the number of landmarks, linear in the number of particles

25

Data Association Problem

Which observation belongs to which landmark?

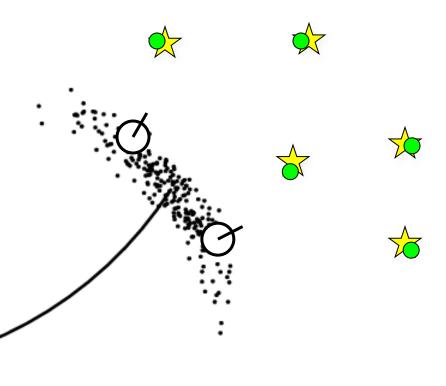

- A robust SLAM solution must consider possible data associations
- Potential data associations depend also on the pose of the robot

Multi-Hypothesis Data Association

 Data association is done on a per-particle basis

 Robot pose error is factored out of data association decisions

Per-Particle Data Association

Was the observation generated by the red or the brown landmark?

P(observation|red) = 0.3

P(observation|brown) = 0.7

- Two options for per-particle data association
 - Pick the most probable match
 - Pick an random association weighted by the observation likelihoods
- If the probability is too low, generate a new landmark

Results - Victoria Park

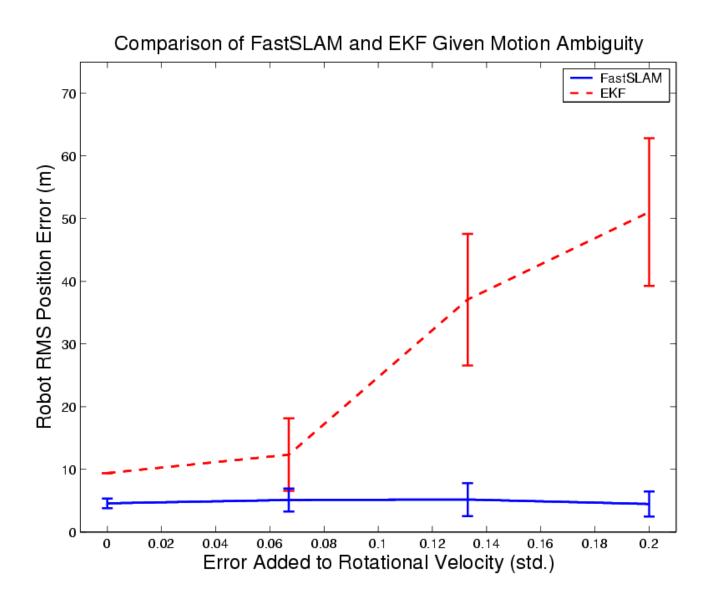

- 4 km traverse
- < 5 m RMS position error
- 100 particles

Blue = GPS
Yellow = FastSLAM

Results - Victoria Park (Video)

Results - Data Association

FastSLAM Summary

- FastSLAM factors the SLAM posterior into low-dimensional estimation problems
 - Scales to problems with over 1 million features
- FastSLAM factors robot pose uncertainty out of the data association problem
 - Robust to significant ambiguity in data association
 - Allows data association decisions to be delayed until unambiguous evidence is collected
- Advantages compared to the classical EKF approach (especially with non-linearities)
- Complexity of O(N log M)
