We can already do a lot with propositional logic. It is, however, annoying that there is no structure in the atomic propositions.

Example:

“All blocks are red”
“There is a block A”
It should follow that “A is red”

But propositional logic cannot handle this.

Idea: We introduce individual variables, predicates, functions, . . . .

→ First-Order Predicate Logic (PL1)
The Alphabet of First-Order Predicate Logic

Symbols:

- Operators: $\neg$, $\lor$, $\land$, $\forall$, $\exists$, $=$
- Variables: $x, x_1, x_2, \ldots, x', x'', \ldots, y, \ldots, z, \ldots$
- Brackets: $(, [, ], )$
- Function symbols (e.g., $weight()$, $color()$)
- Predicate symbols (e.g., $Block()$, $Red()$)
- Predicate and function symbols have an arity (number of arguments).
  - 0-ary predicate = propositional logic atoms: $P, Q, R, \ldots$
  - 0-ary function = constants: $a, b, c, \ldots$
- We assume a countable set of predicates and functions of any arity.
- “$=$” is usually not considered a predicate, but a logical symbol
Terms (represent objects):
1. Every variable is a term.
2. If \( t_1, t_2, \ldots, t_n \) are terms and \( f \) is an \( n \)-ary function, then
   \[
   f(t_1, t_2, \ldots, t_n)
   \]
is also a term.

Terms without variables: ground terms.

Atomic Formulae (represent statements about objects)
1. If \( t_1, t_2, \ldots, t_n \) are terms and \( P \) is an \( n \)-ary predicate, then
   \[
   P(t_1, t_2, \ldots, t_n)
   \]
is an atomic formula.
2. If \( t_1 \) and \( t_2 \) are terms, then \( t_1 = t_2 \) is an atomic formula.

Atomic formulae without variables: ground atoms.
The Grammar of First-Order Predicate Logic (2)

Formulae:

1. Every atomic formula is a formula.
2. If $\varphi$ and $\psi$ are formulae and $x$ is a variable, then

   \[ \neg \varphi, \varphi \land \psi, \varphi \lor \psi, \varphi \Rightarrow \psi, \varphi \Leftrightarrow \psi, \exists x \varphi \text{ and } \forall x \varphi \]

   are also formulae.

   $\forall, \exists$ are as strongly binding as $\neg$.

Propositional logic is part of the PL1 language:

1. Atomic formulae: only 0-ary predicates
2. Neither variables nor quantifiers.

Meaning of PL1-Formulae

Our example: $\forall x [\text{Block}(x) \Rightarrow \text{Red}(x)], \text{Block}(a)$

For all objects $x$: If $x$ is a block, then $x$ is red and $a$ is a block.

Generally:

- Terms are interpreted as objects.
- Universally-quantified variables denote all objects in the universe.
- Existentially-quantified variables represent one of the objects in the universe (made true by the quantified expression).
- Predicates represent subsets of the universe.

Similar to propositional logic, we define interpretations, satisfiability, models, validity, ...
Semantics of PL1-Logic

**Interpretation:** $I = \langle D, \bullet^I \rangle$ where $D$ is an arbitrary, non-empty set and $\bullet^I$ is a function that

- maps $n$-ary function symbols to functions over $D$:
  $$f^I \in [D^n \rightarrow D]$$
- maps individual constants to elements of $D$:
  $$a^I \in D$$
- maps $n$-ary predicate symbols to relations over $D$:
  $$P^I \subseteq D^n$$

**Interpretation of ground terms:**

$$(f(t_1, \ldots, t_n))^I = f^I(t_1^I, \ldots, t_n^I)$$

**Satisfaction of ground atoms** $P(t_1, \ldots, t_n)$:

$$I \models P(t_1, \ldots, t_n) \iff \langle t_1^I, \ldots, t_n^I \rangle \in P^I$$
Example (1)

\[ D = \{d_1, \ldots, d_n \mid n > 1\} \]
\[ a^I = d_1 \]
\[ b^I = d_2 \]
\[ c^I = \ldots \]
\[ Block^I = \{d_1\} \]
\[ Red^I = D \]
\[ I \models Red(b) \]
\[ I \not\models Block(b) \]
Example (2)

\[ D = \{1, 2, 3, \ldots\} \]
\[ 1^I = 1 \]
\[ 2^I = 2 \]
\[ \ldots \]
\[ Even^I = \{2, 4, 6, \ldots\} \]
\[ succ^I = \{(1 \mapsto 2), (2 \mapsto 3), \ldots\} \]
\[ I \models Even(2) \]
\[ I \not\models Even(succ(2)) \]
Semantics of PL1: Variable Assignment

Set of all variables $V$. Function $\alpha : V \mapsto D$

Notation: $\alpha[x/d]$ is the same as $\alpha$ apart from point $x$.

For $x : \alpha[x/d](x) = d$.

Interpretation of terms under $I, \alpha$:

$x^{I,\alpha} = \alpha(x)$

$a^{I,\alpha} = a^I$

$(f(t_1, \ldots, t_n))^{I,\alpha} = f^I(t_1^{I,\alpha}, \ldots, t_n^{I,\alpha})$

Satisfaction of atomic formulae:

$I, \alpha \models P(t_1, \ldots, t_n)$ iff $\langle t_1^{I,\alpha}, \ldots, t_n^{I,\alpha} \rangle \in P^I$
$\alpha = \{(x \mapsto d_1), (y \mapsto d_2)\}$

$I, \alpha \models Red(x)$

$I, \alpha[y/d_1] \models Block(y)$
A formula $\varphi$ is satisfied by an interpretation $I$ and a variable assignment $\alpha$, i.e., $I, \alpha \models \varphi$:

\[
\begin{align*}
I, \alpha \models \top & \iff I, \alpha \not\models \bot \\
I, \alpha \not\models \bot & \iff I, \alpha \models \neg \varphi \\
\end{align*}
\]

... and all other propositional rules as well as

\[
\begin{align*}
I, \alpha \models P(t_1, \ldots, t_n) & \iff \langle t_1^{I,\alpha}, \ldots, t_n^{I,\alpha} \rangle \in P^{I,\alpha} \\
I, \alpha \models \forall x \varphi & \iff \text{for all } d \in D, \ I, \alpha[x/d] \models \varphi \\
I, \alpha \models \exists x \varphi & \iff \text{there exists a } d \in D \text{ with } I, \alpha[x/d] \models \varphi
\end{align*}
\]
Example

\[
T = \{\text{Block}(a), \text{Block}(b), \forall x (\text{Block}(x) \Rightarrow \text{Red}(x))\}
\]
\[
D = \{d_1, \ldots, d_n \mid n > 1\}
\]
\[
a^I = d_1
\]
\[
b^I = d_2
\]
\[
\text{Block}^I = \{d_1\}
\]
\[
\text{Red}^I = D
\]
\[
\alpha = \{(x \mapsto d_1), (y \mapsto d_2)\}
\]

Questions:

1. \(I, \alpha \models \text{Block}(b) \lor \neg \text{Block}(b)?\)
2. \(I, \alpha \models \text{Block}(x) \Rightarrow (\text{Block}(x) \lor \neg \text{Block}(y))?\)
3. \(I, \alpha \models \text{Block}(a) \land \text{Block}(b)?\)
4. \(I, \alpha \models \forall x (\text{Block}(x) \Rightarrow \text{Red}(x))?\)
5. \(I, \alpha \models \top?\)
Free and Bound Variables

\[ \forall x \left[ R(\boxed{y}, \boxed{z}) \land \exists y \left( (\neg P(y, x) \lor R(y, \boxed{z})) \right) \right] \]

The boxed appearances of \( y \) and \( z \) are free. All other appearances of \( x, y, z \) are bound.

Formulae with no free variables are called closed formulae or sentences. We form theories from closed formulae.

**Note:** With closed formulae, the concepts logical equivalence, satisfiability, and implication, etc. are not dependent on the variable assignment \( \alpha \) (i.e., we can always ignore all variable assignments).

With closed formulae, \( \alpha \) can be left out on the left side of the model relationship symbol:

\[ I \models \varphi \]
An interpretation $I$ is called a **model** of $\varphi$ under $\alpha$ if

$$I, \alpha \models \varphi$$

A PL1 formula $\varphi$ can, as in propositional logic, be **satisfiable**, **unsatisfiable**, **falsifiable**, or **valid**.

Analogously, two formulae are **logically equivalent** ($\varphi \equiv \psi$) if for all $I, \alpha$:

$$I, \alpha \models \varphi \text{ iff } I, \alpha \models \psi$$

**Note:** $P(x) \neq P(y)$!

**Logical Implication** is also analogous to propositional logic.

**Question:** How can we define **derivation**?
Because of the quantifiers, we cannot produce the CNF form of a formula directly.

First step: Produce the prenex normal form

\[
\text{quantifier prefix } + (\text{quantifier-free) matrix}
\]

\[
Qx_1Qx_2Qx_3\ldots Qx_n \varphi
\]
Equivalences for the Production of Prenex Normal Form

\[(\forall x \varphi) \land \psi \equiv \forall x (\varphi \land \psi) \text{ if } x \text{ not free in } \psi\]

\[(\forall x \varphi) \lor \psi \equiv \forall x (\varphi \lor \psi) \text{ if } x \text{ not free in } \psi\]

\[(\exists x \varphi) \land \psi \equiv \exists x (\varphi \land \psi) \text{ if } x \text{ not free in } \psi\]

\[(\exists x \varphi) \lor \psi \equiv \exists x (\varphi \lor \psi) \text{ if } x \text{ not free in } \psi\]

\[\forall x \varphi \land \forall x \psi \equiv \forall x (\varphi \land \psi)\]

\[\exists x \varphi \lor \exists x \psi \equiv \exists x (\varphi \lor \psi)\]

\[\neg \forall x \varphi \equiv \exists x \neg \varphi\]

\[\neg \exists x \varphi \equiv \forall x \neg \varphi\]

... and propositional logic equivalents
Production of Prenex Normal Form

1. Eliminate ⇒ and ⇔
2. Move ¬ inwards
3. Move quantifiers outwards

Example:

\[ \neg \forall x [ (\forall x P(x)) \Rightarrow Q(x) ] \]
\[ \rightarrow \neg \forall x [ \neg (\forall x P(x)) \lor Q(x) ] \]
\[ \rightarrow \exists x [ (\forall x P(x)) \land \neg Q(x) ] \]

And now?
\( \varphi[x/t] \) is obtained from \( \varphi \) by replacing all free appearances of \( x \) in \( \varphi \) by \( t \).

**Lemma**: Let \( y \) be a variable that does not appear in \( \varphi \). Then it holds that

\[
\forall x \varphi \equiv \forall y \varphi[x/y] \quad \text{and} \quad \exists x \varphi \equiv \exists y \varphi[x/y]
\]

**Theorem**: There exists an algorithm that calculates the prenex normal form of any formula.
Idea: **Elimination of existential quantifiers** by applying a function that produces the “right” element.

**Theorem (Skolem Normal Form):** Let $\varphi$ be a closed formula in prenex normal form such that all quantified variables are pair-wise distinct and the function symbols $g_1, g_2, \ldots$ do not appear in $\varphi$. Let

$$\varphi = \forall x_1 \cdots \forall x_i \exists y \psi,$$

then $\varphi$ is satisfiable iff

$$\varphi' = \forall x_1 \cdots \forall x_i \psi \left[ \frac{y}{g_i(x_1, \ldots, x_i)} \right]$$

is satisfiable.

**Example:** $\forall x \exists y [P(x) \Rightarrow Q(y)] \rightarrow \forall x [P(x) \Rightarrow Q(g(x))]$
Skolem Normal Form: Prenex normal form without existential quantifiers. Notation: $\varphi^*$ is the SNF of $\varphi$.

Theorem: It is possible to calculate the Skolem normal form of every closed formula $\varphi$.

Example: $\exists x ((\forall x P(x)) \land \neg Q(x))$ develops as follows:

$\exists y ((\forall x P(x)) \land \neg Q(y))$

$\exists y (\forall x (P(x) \land \neg Q(x)))$

$\forall x (P(x) \land \neg Q(g_0))$

Note: This transformation is not an equivalence transformation; it only preserves satisfiability!

Note: ... and is not unique.
We have: **Skolem Normal Form**

*quantifier prefix* + *(quantifier-free) matrix*

\[ \forall x_1 \forall x_2 \forall x_3 \cdots \forall x_n \, \varphi \]

1. Put Matrix \( \varphi \) into CNF using propositional logic equivalences.
2. Eliminate universal quantifiers.
3. Eliminate conjunction symbol.
4. Rename variables so that no variable appears in more than one clause.

**Theorem:** It is possible to calculate the clausal form of every closed formula \( \varphi \).

**Note:** Same remarks as for SNF
Conversion to Clausal Form (1)

Everyone who loves all animals is loved by someone:

$$\forall x (\forall y (\text{Animal}(y) \Rightarrow \text{Loves}(x, y))) \Rightarrow [\exists y \text{Loves}(y, x)]$$

1. Eliminate biconditionals and implications

$$\forall x (\neg [\forall y (\neg \text{Animal}(y) \vee \text{Loves}(x, y))] \vee [\exists y \text{Loves}(y, x)])$$

2. Move $\neg$ inwards: $\neg \forall xp \equiv \exists x \neg p$, $\neg \exists xp \equiv \forall x \neg p$

$$\forall x ([\exists y (\neg (\neg \text{Animal}(y) \vee \text{Loves}(x, y)))] \vee [\exists y \text{Loves}(y, x)])$$

$$\forall x ([\exists y (\neg \neg \text{Animal}(y) \wedge \neg \text{Loves}(x, y))] \vee [\exists y \text{Loves}(y, x)])$$

$$\forall x ([\exists y (\text{Animal}(y) \wedge \neg \text{Loves}(x, y))] \vee [\exists y \text{Loves}(y, x)])$$
3. Standardize variables: each quantifier should use a different one

$$\forall x (\exists y (\text{Animal}(y) \land \neg \text{Loves}(x, y)) \lor \exists z \text{Loves}(z, x))$$

4. Prenex norm form: all quantifiers in front of the matrix:

$$\forall x \exists y \exists z ((\text{Animal}(y) \land \neg \text{Loves}(x, y)) \lor \text{Loves}(z, x))$$

5. Skolemize: Each existential variable is replaced by a Skolem function of the enclosing universally quantified variables:

$$\forall x (\text{Animal}(f(x)) \land \neg \text{Loves}(x, f(x)) \lor \text{Loves}(g(x), x))$$

6. Distribute $\land$ over $\lor$:

$$\forall x ((\text{Animal}(f(x)) \lor \text{Loves}(g(x), x)) \land (\neg \text{Loves}(x, f(x)) \lor \text{Loves}(g(x), x)))$$
7. Eliminate universal quantification (implicitly assumed):

\[ ([\text{Animal}(f(x)) \lor \text{Loves}(g(x), x)] \land [\neg \text{Loves}(x, g(x)) \lor \text{Loves}(g(x), x)]) \]  

8. Eliminate conjunction (and transform to set of disjunctions):

\{ [\text{Animal}(f(x)) \lor \text{Loves}(g(x), x)], [\neg \text{Loves}(x, g(x)) \lor \text{Loves}(g(x), x)] \}  

9. Normalize variables:

\{ [\text{Animal}(f(x)) \lor \text{Loves}(g(x), x)], [\neg \text{Loves}(y, g(y)) \lor \text{Loves}(g(y), y)] \}
Assumption: KB is a set of clauses.

Due to commutativity, associativity, and idempotence of $\lor$, clauses can also be understood as sets of literals. The empty set of literals is denoted by $\square$ (and denotes falsity).

Set of clauses: $\Delta$

Set of literals: $C$, $D$

Literal: $l$

Negation of a literal: $\overline{l}$
Propositional Resolution

\[
\begin{array}{c}
C_1 \cup \{l\}, C_2 \cup \{\overline{l}\} \\
\hline
C_1 \cup C_2
\end{array}
\]

\(C_1 \cup C_2\) are called resolvents of the parent clauses \(C_1 \cup \{l\}\) and \(C_2 \cup \{\overline{l}\}\). \(l\) and \(\overline{l}\) are the resolution literals.

Example: \(\{a, b, \neg c\}\) resolves with \(\{a, d, c\}\) to \(\{a, b, d\}\).

Notation: \(R(\Delta) = \Delta \cup \{C \mid C \text{ is a resolvent of two clauses from } \Delta\}\)
Examples

\{
\{\text{Nat}(s(0)), \neg\text{Nat}(0)\}, \{\text{Nat}(0)\}\} \vdash \{\text{Nat}(s(0))\}
\{
\{\text{Nat}(s(0)), \neg\text{Nat}(x)\}, \{\text{Nat}(0)\}\} \vdash \{\text{Nat}(s(0))\}
\{
\{\text{Nat}(s(x)), \neg\text{Nat}(x)\}, \{\text{Nat}(0)\}\} \vdash \{\text{Nat}(s(0))\}
\}

We need \text{unification}, a way to make literals identical.

Based on the notion of \text{substitution}, e.g., \{\frac{x}{0}\}.
A substitution $s = \{ \frac{v_1}{t_1}, \ldots, \frac{v_n}{t_n} \}$ substitutes variables $v_i$ by terms $t_i$ ($t_i$ must not contain $v_i$).

Applying a substitution $s$ to an expression $\varphi$ yields the expression $\varphi s$ which is $\varphi$ with all occurrences of $v_i$ replaced by $t_i$ for all $i$. 
Substitution Examples

\[ P(x, f(y), b) \]

\[ P(z, f(w), b) \quad s = \{ \frac{x}{z}, \frac{y}{w} \} \]

\[ P(x, f(a), b) \quad s = \{ y \} \]

\[ P(g(z), f(a), b) \quad s = \left\{ \frac{x}{g(z)}, \frac{y}{a} \right\} \]

\[ P(c, f(a), a) \]

Reminder: \( x, y, z, \ldots \) are variables, \( a, b, c, \ldots \) are constants, \( f, g, \ldots \) are functions.
Composing substitutions $s_1$ and $s_2$ gives $s_1s_2$ which is that substitution obtained by first applying $s_2$ to the terms in $s_1$ and adding remaining term/variable pairs (not occurring in $s_1$) to $s_1$.

Example: \[
\left\{ \frac{z}{g(x,y)} \right\} \left\{ \frac{x}{a}, \frac{y}{b}, \frac{w}{c}, \frac{z}{d} \right\} = \left\{ \frac{z}{g(a,b)}, \frac{x}{a}, \frac{y}{b}, \frac{w}{c} \right\}
\]

Application example: $P(x, y, z) \rightarrow P(a, b, g(a, b))$
Properties of substitutions

For a formula $\varphi$ and substitutions $s_1, s_2$

$$(\varphi s_1)s_2 = \varphi(s_1s_2)$$

$$(s_1s_2)s_3 = s_1(s_2s_3)$$

$\varphi$-associativity

$s_1s_2 \neq s_2s_1$

no commutativity!
Unification

Unifying a set of expressions \( \{w_i\} \)

Find substitution \( s \) such that \( w_i s = w_j s \) for all \( i, j \)

Example

\( \{P(x, f(y), b), P(x, f(b), b)\} \)

\( s = \{ \frac{y}{b}, \frac{z}{a} \} \) not the simplest unifier

\( s = \{ \frac{y}{b} \} \) most general unifier (mgu)

The most general unifier, the mgu, \( g \) of \( \{w_i\} \) has the property that if \( s \) is any unifier of \( \{w_i\} \) then there exists a substitution \( s' \) such that

\( \{w_i\} s = \{w_i\} gs' \)

Property: The common expression produced is unique up to alphabetic variants (variable renaming) for all mgus.
The disagreement set of a set of expressions \( \{ w_i \} \) is the set of sub-terms \( \{ t_i \} \) of \( \{ w_i \} \) at the first position in \( \{ w_i \} \) for which the \( \{ w_i \} \) disagree.

Examples

\[
\{ P(x, a, f(y)), P(v, b, z) \} \quad \text{gives} \quad \{ x, v \}
\]

\[
\{ P(x, a, f(y)), P(x, b, z) \} \quad \text{gives} \quad \{ a, b \}
\]

\[
\{ P(x, y, f(y)), P(x, b, z) \} \quad \text{gives} \quad \{ y, b \}
\]
Unification Algorithm

**Unify**(Terms):

1. $k \leftarrow 0$
2. $T_k = \text{Terms}$
3. $s_k = \emptyset$
4. If $T_k$ is a singleton, then return $s_k$.
5. Let $D_k$ be the disagreement set of $T_k$.
6. If there exists a var $v_k$ and a term $t_k$ in $D_k$ such that $v_k$ does not occur in $t_k$, continue. Otherwise, exit with failure.
7. $s_{k+1} \leftarrow s_k\{\frac{v_k}{t_k}\}$
8. $T_{k+1} \leftarrow T_k\{\frac{v_k}{t_k}\}$
9. $k \leftarrow k + 1$
Example

\{P(x, f(y), y), P(z, f(b), b)\}
Binary Resolution

\[ C_1 \cup \{l_1\}, C_2 \cup \{\overline{l_2}\} \]

\[ [C_1 \cup C_2]s \]

where \( s = \text{mgu}(l_1, l_2) \), the most general unifier \([C_1 \cup C_2]s\) is the resolvent of the parent clauses \( C_1 \cup \{l_1\} \) and \( C_2 \cup \{\overline{l_2}\} \).

\( C_1 \cup \{l_1\} \) and \( C_2 \cup \{\overline{l_2}\} \) do not share variables \( l_1 \) and \( l_2 \) are the resolution literals.

Examples:

\[
\{\{\text{Nat}(s(0)), \neg \text{Nat}(0)\}, \{\text{Nat}(0)\}\} \vdash \{\text{Nat}(s(0))\}
\]

\[
\{\{\text{Nat}(s(0)), \neg \text{Nat}(x)\}, \{\text{Nat}(0)\}\} \vdash \{\text{Nat}(s(0))\}
\]

\[
\{\{\text{Nat}(s(x)), \neg \text{Nat}(x)\}, \{\text{Nat}(0)\}\} \vdash \{\text{Nat}(s(0))\}
\]
Some Further Examples

Resolve \( \{P(x), Q(f(x))\} \) and \( \{R(g(x)), \neg Q(f(a))\} \)

Standardizing the variables apart gives \( \{P(x), Q(f(x))\} \) and \( \{R(g(y)), \neg Q(f(a))\} \)

Substitution \( s = \{\frac{x}{a}\} \) Resolvent \( \{P(a), R(g(y))\} \)

Resolve \( \{P(x), Q(x, y)\} \) and \( \{-P(a), \neg R(b, z)\} \)

Standardizing the variables apart

Substitution \( s = \{\frac{x}{a}\} \) and Resolvent \( \{Q(a, y), \neg R(b, z)\} \)
\[
\frac{C_1 \cup \{l_1\} \cup \{l_2\}}{[C_1 \cup \{l_1\}]s}
\]

where \( s = \text{mgu}(l_1, l_2) \) is the most general unifier.

**Needed because:**

\[
\{\{P(u), P(v)\}, \{\neg P(x), \neg P(y)\}\} \models \Box
\]

but \( \Box \) cannot be derived by binary resolution

**Factoring yields:**

\( \{P(u)\} \) and \( \{\neg P(x)\} \) whose resolvent is \( \Box \).
Notation: \( R(\Delta) = \Delta \cup \{ C \mid C \text{ is a resolvent or a factor of two clauses from } \Delta \} \)

We say \( D \) can be derived from \( \Delta \), i.e.,

\[
\Delta \vdash D,
\]

if there exist \( C_1, C_2, C_3, \ldots, C_n = D \) such that

\[
C_i \in R(\Delta \cup \{ C_1, \ldots, C_{i-1} \}) \text{ for } 1 \leq i \leq n.
\]
Properties of Resolution

Lemma: (soundness) If $\Delta \vdash D$, then $\Delta \models D$.

Lemma: resolution is refutation-complete:
$\Delta$ is unsatisfiable implies $\Delta \vdash \Box$.

Theorem: $\Delta$ is unsatisfiable iff $\Delta \vdash \Box$.

Technique: to prove that $\Delta \models C$ negate $C$ and prove that $\Delta \cup \{\neg C\} \vdash \Box$. 
Recursive Enumeration and Decidability

Based on the result, we can construct a semi-decision procedure for validity, i.e., we can give a (rather inefficient) algorithm that enumerates all valid formulae step by step.

Theorem: The set of valid (and unsatisfiable) formulae in PL1 is recursively enumerable.

What about satisfiable formulae?

Theorem (undecidability of PL1): It is undecidable, whether a formula of PL1 is valid.

(Proof by reduction from PCP)

Corollary: The set of satisfiable formulae in PL1 is not recursively enumerable.

In other words: If a formula is valid (or follows logically from a set of formulae), we can effectively confirm this. Otherwise, we can end up in an infinite loop (producing resolvents without end).
From Russell and Norvig:

The law says it is a crime for an American to sell weapons to hostile nations. The country Nono, an enemy of America, has some missiles, and all of its missiles were sold to it by Colonel West, who is American.

Prove that Col. West is a criminal.
... it is a crime for an American to sell weapons to hostile nations:

\[ \text{American}(x) \land \text{weapon}(y) \land \text{Sells}(x, y, z) \land \text{Hostile}(z) \Rightarrow \text{Criminal}(x) \]

Nono ... has some missiles, i.e., \( \exists x \text{Owns}(\text{Nono}, x) \land \text{Missile}(x) \):

\( \text{Owns}(\text{Nono}, M_1) \text{ and } \text{Missile}(M_1) \)

... all of its missiles were sold to it by Colonel West.

\[ \forall x \text{Missiles}(x) \land \text{Owns}(\text{Nono}, x) \Rightarrow \text{Sells}(\text{West}, x, \text{Nono}) \]

Missiles are weapons:

\[ \text{Missile}(x) \Rightarrow \text{Weapon}(x) \]

An enemy of America counts as “hostile”:

\[ \text{Enemy}(x, \text{America}) \Rightarrow \text{Hostile}(x) \]

West, who is American ...

\( \text{American}(\text{West}) \)

The country Nono, an enemy of America

\( \text{Enemy}(\text{Nono}, \text{America}) \)
An Example

\[ \neg \text{American}(x) \lor \neg \text{Weapon}(y) \lor \neg \text{Sells}(x,y,z) \lor \neg \text{Hostile}(z) \lor \text{Criminal}(x) \]

\[ \neg \text{American}(x) \lor \neg \text{Weapon}(y) \lor \neg \text{Sells}(x,y,z) \lor \neg \text{Hostile}(z) \]

\[ \neg \text{Missile}(x) \lor \text{Weapon}(x) \]

\[ \neg \text{Missile}(x) \lor \neg \text{Owns}(Nono,x) \lor \text{Sells}(West,x,Nono) \]

\[ \neg \text{Missile}(M_1) \]

\[ \neg \text{Missile}(M_1) \lor \neg \text{Owns}(Nono,M_1) \lor \neg \text{Hostile}(Nono) \]

\[ \neg \text{Enemy}(x,America) \lor \text{Hostile}(x) \]

\[ \neg \text{Enemy}(Nono,America) \]

\[ \neg \text{Enemy}(Nono,America) \]

\[ \neg \text{Enemy}(Nono,America) \]

\[ \neg \text{Enemy}(Nono,America) \]

\[ \neg \text{Enemy}(Nono,America) \]

\[ \neg \text{Enemy}(Nono,America) \]

\[ \neg \text{Enemy}(Nono,America) \]
Closing Remarks: Processing

- **PL1-Resolution**: forms the basis of
  - most state of the art theorem provers for PL1
  - the programming language Prolog
    - only Horn clauses
    - considerably more efficient methods.
  - not dealt with: search/resolution strategies

- **Finite theories**: In applications, we often have to deal with a fixed set of objects. **Domain closure axiom**:
  \[
  \forall x [x = c_1 \lor x = c_2 \lor \ldots \lor x = c_n]
  \]
- Translation into finite propositional theory is possible.
Closing Remarks: Possible Extensions

- PL1 is definitely very expressive, but in some circumstances we would like more . . .

- **Second-Order Logic**: Also over predicate quantifiers
  \[ \forall x, y[(x = y) \Leftrightarrow \{\forall p[p(x) \Leftrightarrow p(y)]\}] \]

- Validity is no longer semi-decidable

- **Lambda Calculus**: Definition of predicates, e.g.,
  \[ \lambda x, y[\exists z P(x, z) \land Q(z, y)] \text{ defines a new predicate of arity 2} \]

- Reducible to PL1 through Lambda-Reduction

- **Uniqueness quantifier**: \( \exists! x \varphi(x) \) - there is exactly one \( x \) . . .

- Reduction to PL1:
  \[ \exists x[\varphi(x) \land \forall y(\varphi(y) \Rightarrow x = y)] \]
Summary

- PL1 makes it possible to structure statements, thereby giving us considerably more expressive power than propositional logic.
- Formulae consist of terms and atomic formulae, which, together with connectors and quantifiers, can be put together to produce formulae.
- Interpretations in PL1 consist of a universe and an interpretation function.
- Resolution is sound and refutation complete.
- Validity in PL1 is not decidable (it is only semi-decidable).
