Kalman Filter

- Bayes filter with **Gaussians**
- Developed in the late 1950's
- Most relevant Bayes filter variant in practice
- Applications range from economics, weather forecasting, satellite navigation to robotics and many more.
- The Kalman filter “algorithm” is a couple of **matrix multiplications!**

Gaussians

$p(x) \sim N(\mu, \sigma^2)$:

$$p(x) = \frac{1}{\sqrt{2\pi}\sigma} e^{-\frac{1}{2\sigma^2}(x-\mu)^2}$$

Univariate

$p(\mathbf{x}) \sim N(\mu, \Sigma)$:

$$p(\mathbf{x}) = \frac{1}{(2\pi)^{d/2} |\Sigma|^{1/2}} e^{-\frac{1}{2}(\mathbf{x}-\mu)^t \Sigma^{-1} (\mathbf{x}-\mu)}$$

Multivariate

Gaussians

2D

$$C = \begin{bmatrix} 0.020 & 0.013 \\ 0.013 & 0.020 \end{bmatrix}$$

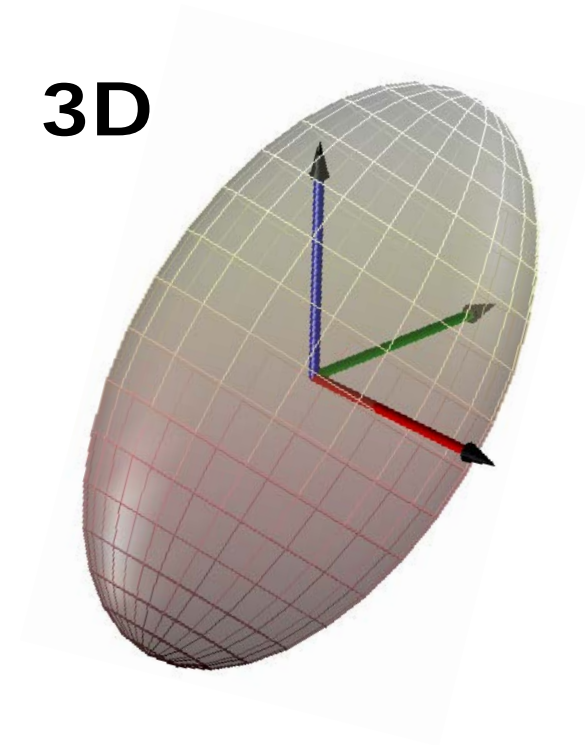

$$\lambda_1 = 0.007$$

$$\lambda_2 = 0.033$$

$$\rho = \sigma_{XY} / \sigma_X \sigma_Y = 0.673$$

3D

Properties of Gaussians

- Univariate case

$$\left. \begin{array}{l} X \sim N(\mu, \sigma^2) \\ Y = aX + b \end{array} \right\} \Rightarrow Y \sim N(a\mu + b, a^2 \sigma^2)$$

$$\left. \begin{array}{l} X_1 \sim N(\mu_1, \sigma_1^2) \\ X_2 \sim N(\mu_2, \sigma_2^2) \end{array} \right\} \Rightarrow p(X_1) \cdot p(X_2) \sim N\left(\frac{\sigma_2^2}{\sigma_1^2 + \sigma_2^2} \mu_1 + \frac{\sigma_1^2}{\sigma_1^2 + \sigma_2^2} \mu_2, \frac{1}{\sigma_1^{-2} + \sigma_2^{-2}}\right)$$

Properties of Gaussians

- Multivariate case

$$\left. \begin{array}{l} X \sim N(\mu, \Sigma) \\ Y = AX + B \end{array} \right\} \Rightarrow Y \sim N(A\mu + B, A\Sigma A^T)$$

$$\left. \begin{array}{l} X_1 \sim N(\mu_1, \Sigma_1) \\ X_2 \sim N(\mu_2, \Sigma_2) \end{array} \right\} \Rightarrow p(X_1) \cdot p(X_2) \sim N\left(\frac{\Sigma_2}{\Sigma_1 + \Sigma_2} \mu_1 + \frac{\Sigma_1}{\Sigma_1 + \Sigma_2} \mu_2, \frac{1}{\Sigma_1^{-1} + \Sigma_2^{-1}}\right)$$

(where division "-" denotes matrix inversion)

- We **stay Gaussian** as long as we start with Gaussians and perform only **linear transformations**

Discrete Kalman Filter

Estimates the state x of a discrete-time controlled process that is governed by the linear stochastic difference equation

$$x_t = A_t x_{t-1} + B_t u_t + \varepsilon_t$$

with a measurement

$$z_t = C_t x_t + \delta_t$$

Components of a Kalman Filter

A_t

Matrix ($n \times n$) that describes how the state evolves from $t-1$ to t without controls or noise.

B_t

Matrix ($n \times l$) that describes how the control u_t changes the state from $t-1$ to t .

C_t

Matrix ($k \times n$) that describes how to map the state x_t to an observation z_t .

ε_t

Random variables representing the process and measurement noise that are assumed to be independent and normally distributed with covariance Q_t and R_t respectively.

δ_t

Linear Gaussian Systems: Initialization

Initial belief is normally distributed:

$$\mathit{bel}(x_0) = N(x_0; \mu_0, \Sigma_0)$$

Linear Gaussian Systems: Dynamics

Dynamics are linear functions of the state and the control plus additive noise:

$$x_t = A_t x_{t-1} + B_t u_t + \varepsilon_t$$

$$p(x_t | u_t, x_{t-1}) = N(x_t; A_t x_{t-1} + B_t u_t, Q_t)$$

$$\begin{array}{ccc} \overline{bel}(x_t) = \int p(x_t | u_t, x_{t-1}) & & bel(x_{t-1}) dx_{t-1} \\ \Downarrow & & \Downarrow \\ \sim N(x_t; A_t x_{t-1} + B_t u_t, Q_t) & \sim & N(x_{t-1}; \mu_{t-1}, \Sigma_{t-1}) \end{array}$$

Kalman Filter Summary

- Only two parameters describe belief about the state of the system
- **Highly efficient:** Polynomial in the measurement dimensionality k and state dimensionality n :

$$O(k^{2.376} + n^2)$$

- **Optimal for linear Gaussian systems!**
- However: Most robotics systems are **nonlinear!**
- Can only model unimodal beliefs
