

Introduction to Mobile Robotics

Bayes Filter – Particle Filter and Monte Carlo Localization

Lukas Luft, Wolfram Burgard

Motivation

- Recall: Discrete filter
 - Discretize the continuous state space
 - High memory complexity
 - Fixed resolution (does not adapt to the belief)
- Particle filters are a way to **efficiently** represent **non-Gaussian distribution**
- Basic principle
 - Set of state hypotheses (“particles”)
 - Survival-of-the-fittest

Sample-based Localization (sonar)

Mathematical Description

- Set of weighted samples

$$S = \left\{ \left\langle s^{[i]}, w^{[i]} \right\rangle \mid i = 1, \dots, N \right\}$$

State hypothesis

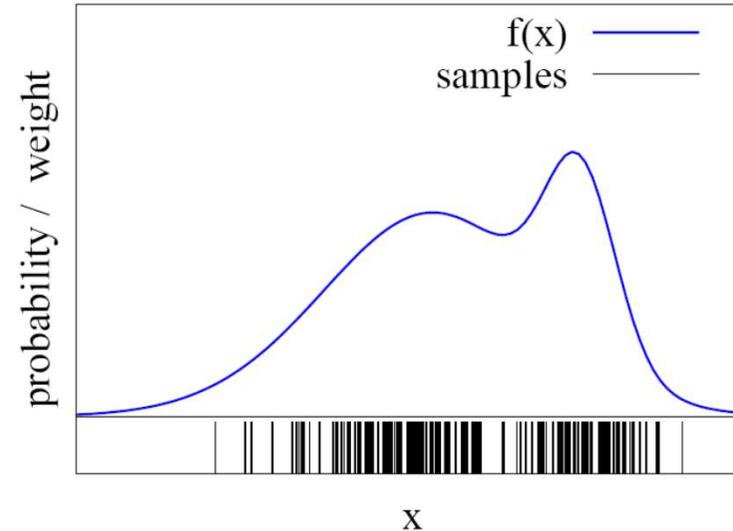

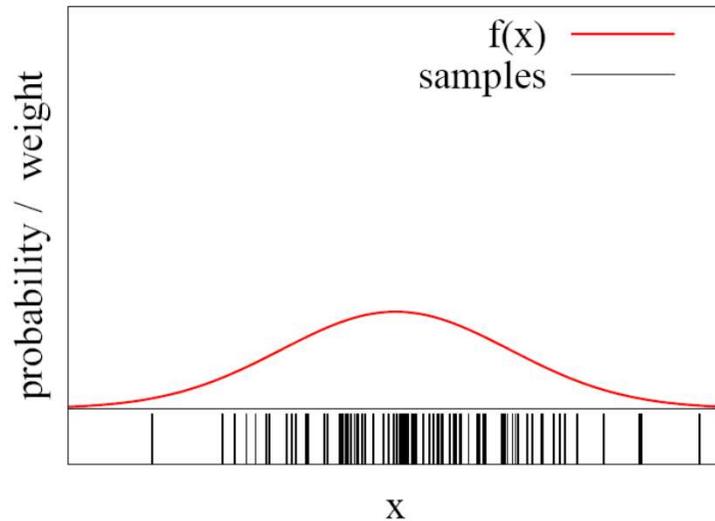

Importance weight

- The samples represent the posterior

$$p(x) = \sum_{i=1}^N w_i \cdot \delta_{s^{[i]}}(x)$$

Function Approximation

- Particle sets can be used to approximate functions

- The more particles fall into an interval, the higher the probability of that interval
- How to draw samples from a function/distribution?

Bayes filter with particle sets

- Measurement update

$$bel(x) \leftarrow p(z|x)\overline{bel}(x)$$

$$= p(z|x) \sum_i w_i \delta_{s^{[i]}}(x) = \sum_i p(z|s^{[i]}) w_i \delta_{s^{[i]}}(x)$$

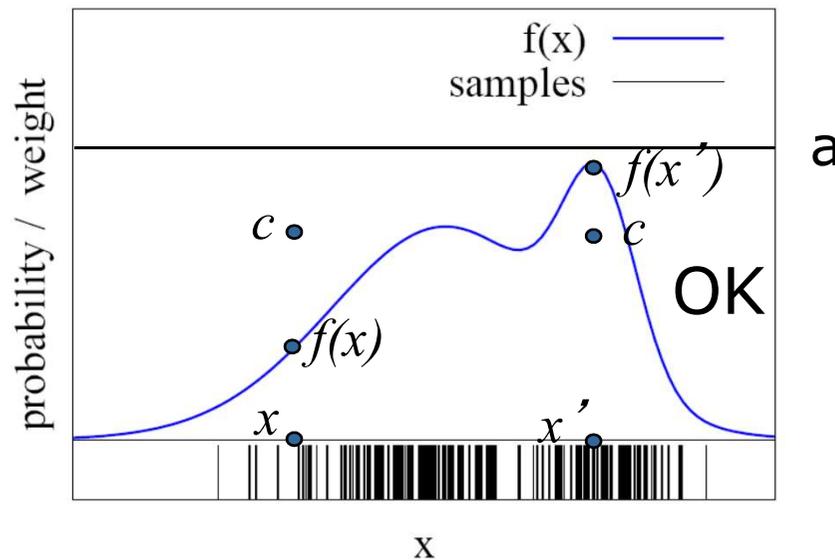

- Motion update

$$\overline{bel}(x) \leftarrow \int p(x|u, x^-) bel(x^-) dx^-$$

$$= \int p(x|u, x^-) \sum_i w_i \delta_{s^{[i]}}(x^-) dx^- = \sum_i p(x|u, s^{[i]}) w_i$$

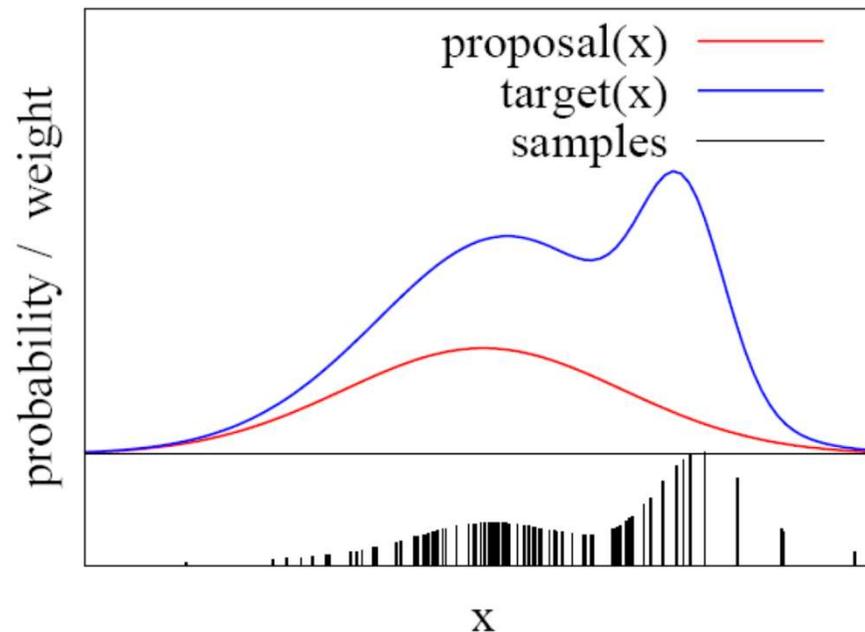

Rejection Sampling

- Let us assume that $f(x) < a$ for all x
- Sample x from a uniform distribution
- Sample c from $[0, a]$
- if $f(x) > c$ keep the sample
otherwise reject the sample

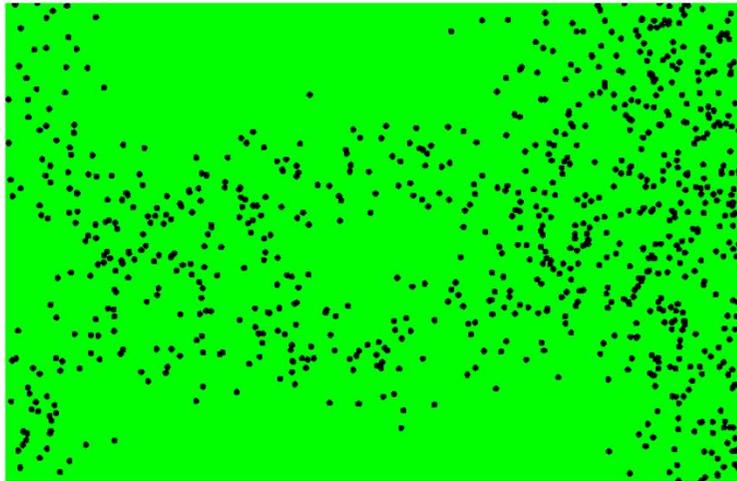

Importance Sampling Principle

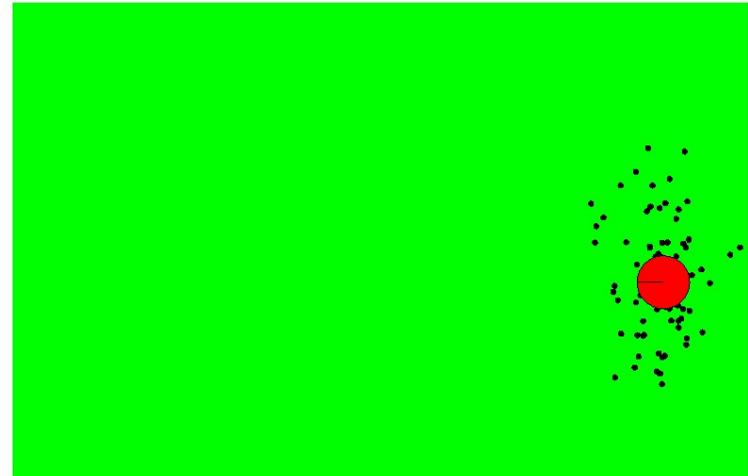

- We can even use a different distribution g to generate samples from f
- By introducing an importance weight w , we can account for the “differences between g and f ”
- $w = f / g$
- f is called target
- g is called proposal
- Pre-condition:
 $f(x) > 0 \rightarrow g(x) > 0$
- Derivation: See webpage

Importance Sampling with Resampling

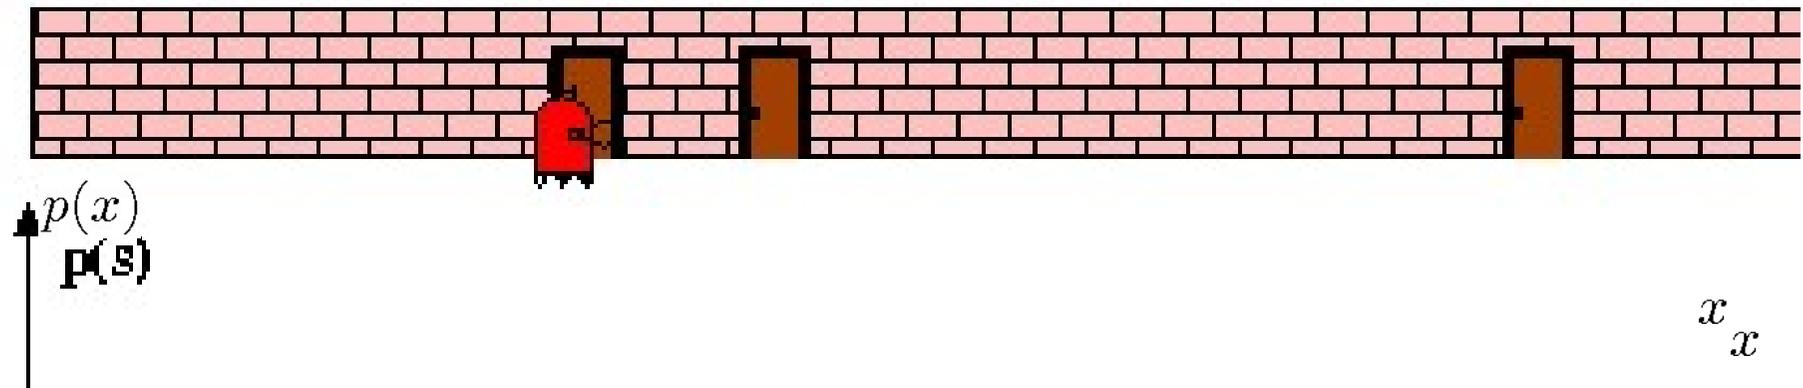

Weighted samples

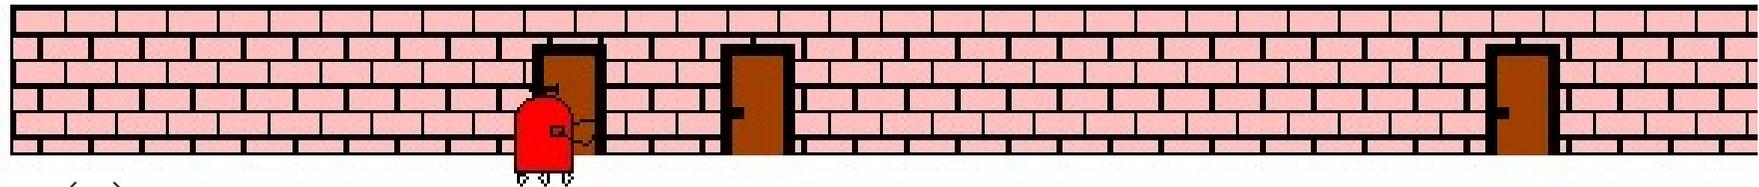

After resampling

Particle Filters

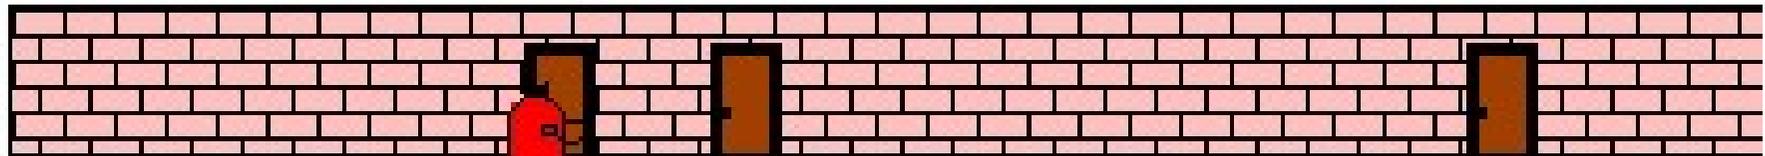

Sensor Information: Importance Sampling

$$\begin{aligned}
 Bel(x) &\leftarrow \alpha p(z | x) Bel^-(x) \\
 w &\leftarrow \frac{\alpha p(z | x) Bel^-(x)}{Bel^-(x)} = \alpha p(z | x)
 \end{aligned}$$

$p(x)$
 $p(s)$

x

$p(z | x)$
 $P(o|s)$

x

$p(x | z)$

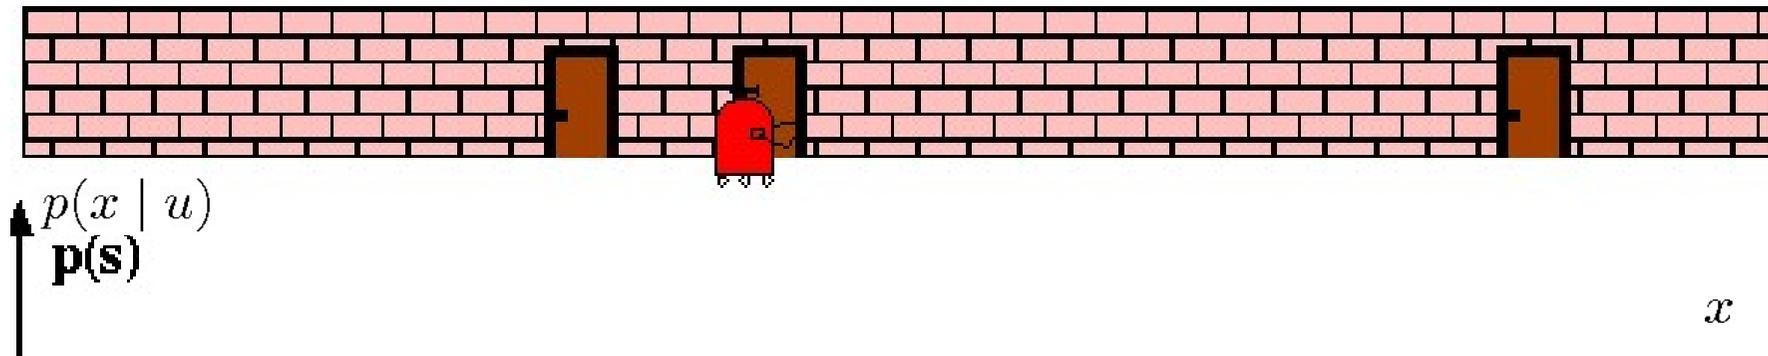

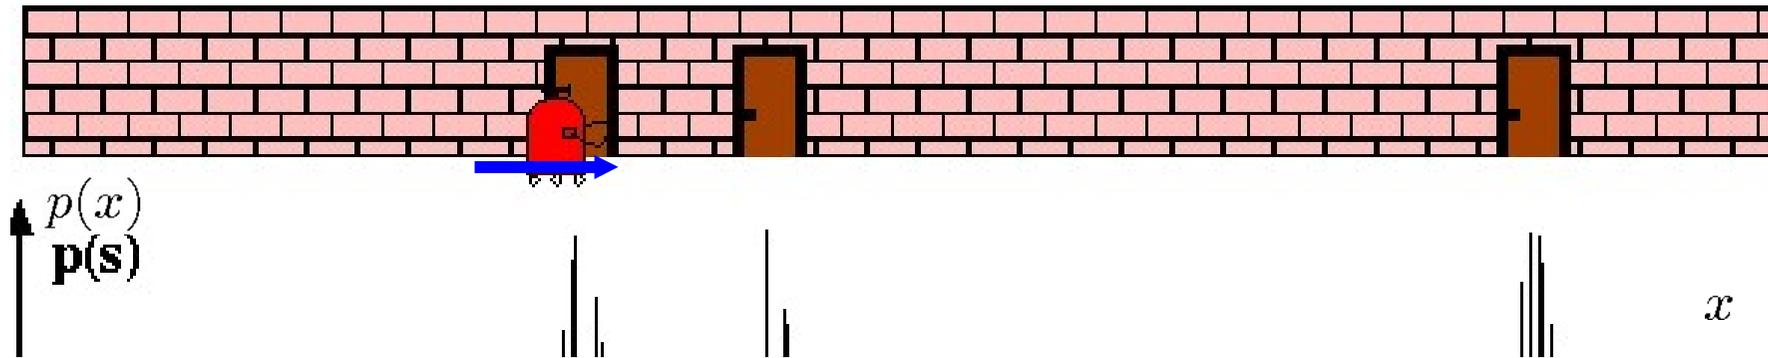

$p(s)$

x

Robot Motion

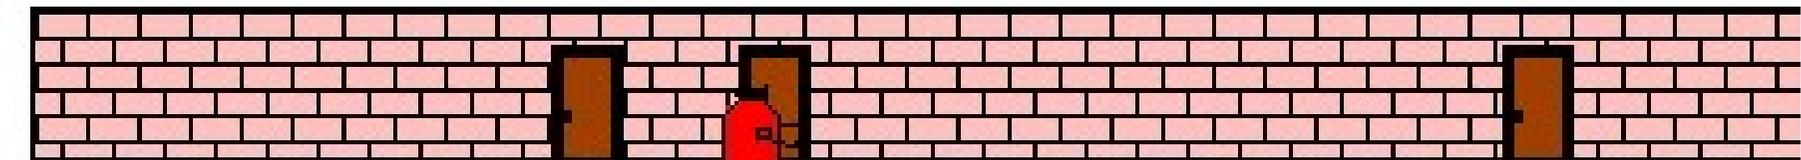

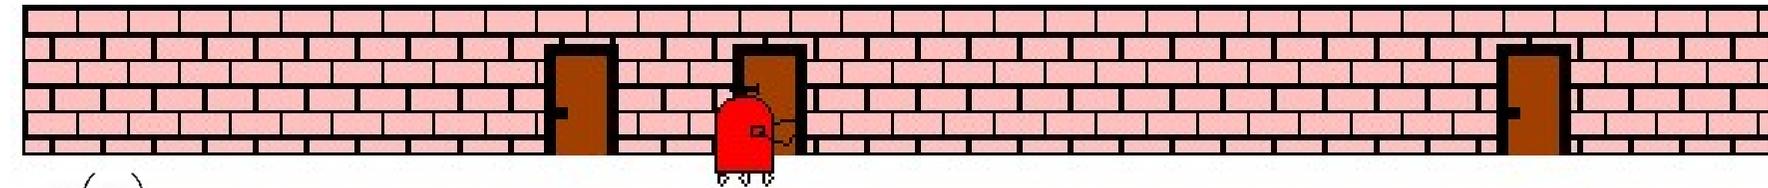

$$Bel^-(x) \leftarrow \int p(x|u, x') Bel(x') dx'$$

Sensor Information: Importance Sampling

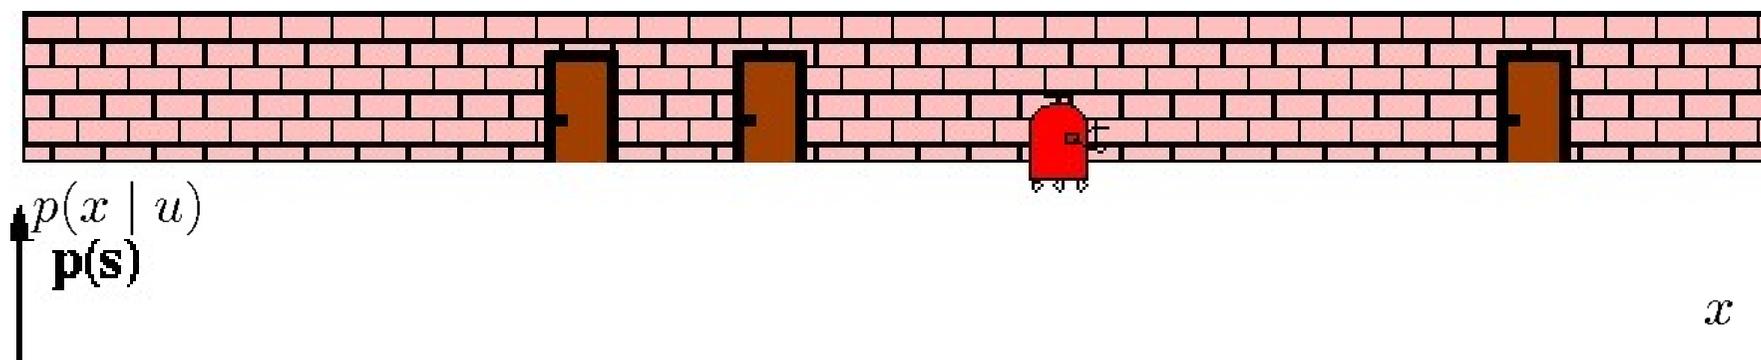

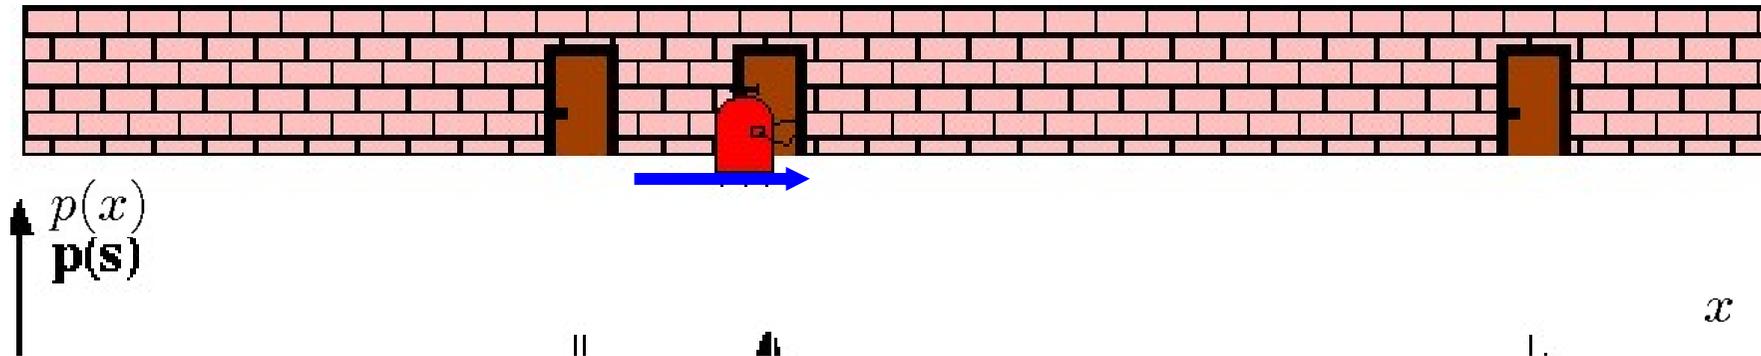

$$Bel(x) \leftarrow \alpha p(z|x) Bel^-(x)$$

$$w \leftarrow \frac{\alpha p(z|x) Bel^-(x)}{Bel^-(x)} = \alpha p(z|x)$$

Robot Motion

$$Bel^-(x) \leftarrow \int p(x|u, x') Bel(x') dx'$$

Particle Filter Algorithm

- Sample the next generation for particles using the proposal distribution
- Compute the importance weights :
$$weight = target\ distribution / proposal\ distribution$$
- Resampling: “Replace unlikely samples by more likely ones”

Particle Filter Algorithm

1. Algorithm **particle_filter**(S_{t-1}, u_t, z_t):
2. $S_t = \emptyset, \quad \eta = 0$
3. **For** $i = 1, \dots, n$ *Generate new samples*
4. Sample index $j(i)$ from the discrete distribution given by w_{t-1}
5. Sample x_t^j from $p(x_t | x_{t-1}, u_t)$ using $x_{t-1}^{j(i)}$ and u_t
6. $w_t^j = p(z_t | x_t^j)$ *Compute importance weight*
7. $\eta = \eta + w_t^j$ *Update normalization factor*
8. $S_t = S_t \cup \{ \langle x_t^j, w_t^j \rangle \}$ *Add to new particle set*
9. **For** $i = 1, \dots, n$
10. $w_t^j = w_t^j / \eta$ *Normalize weights*

Particle Filter Algorithm

$$Bel(x_t) = \eta p(z_t | x_t) \int p(x_t | x_{t-1}, u_t) Bel(x_{t-1}) dx_{t-1}$$

draw x_{t-1}^i from $Bel(x_{t-1})$

draw x_t^i from $p(x_t | x_{t-1}^i, u_t)$

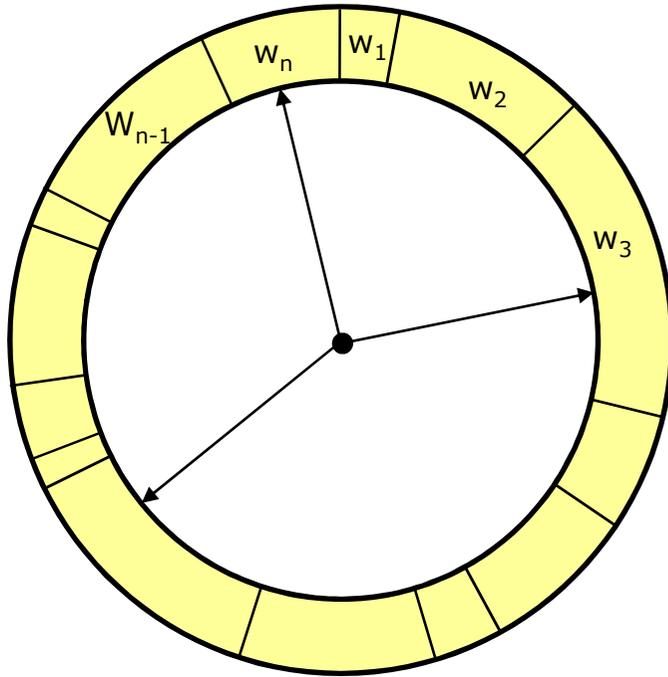

Importance factor for x_t^i :

$$\begin{aligned} w_t^i &= \frac{\text{target distribution}}{\text{proposal distribution}} \\ &= \frac{\eta p(z_t | x_t) p(x_t | x_{t-1}^i, u_t) Bel(x_{t-1}^i)}{p(x_t | x_{t-1}^i, u_t) Bel(x_{t-1}^i)} \\ &\propto p(z_t | x_t) \end{aligned}$$

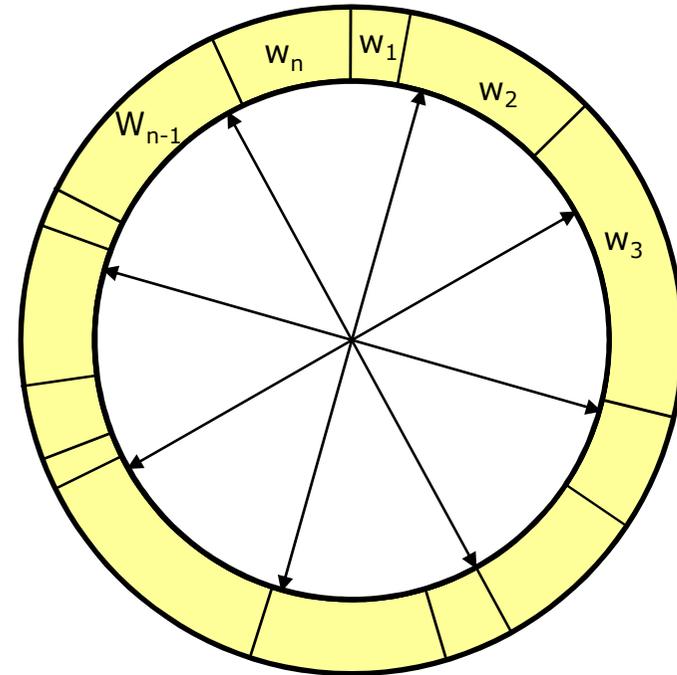

Resampling

- **Given**: Set S of weighted samples.
- **Wanted** : Random sample, where the probability of drawing x_i is given by w_i .
- Typically done n times with replacement to generate new sample set S' .

Resampling

- Roulette wheel
- Binary search, $n \log n$

- Stochastic universal sampling
- Systematic resampling
- Linear time complexity
- Easy to implement, low variance

Resampling Algorithm

1. Algorithm **systematic_resampling**(S, n):

2. $S' = \emptyset, c_1 = w^1$

3. **For** $i = 2 \dots n$ *Generate cdf*

4. $c_i = c_{i-1} + w^i$

5. $u_1 \sim U[0, n^{-1}]$, $i = 1$ *Initialize threshold*

6. **For** $j = 1 \dots n$ *Draw samples ...*

7. **While** ($u_j > c_i$) *Skip until next threshold reached*

8. $i = i + 1$

9. $S' = S' \cup \{ \langle x^i, n^{-1} \rangle \}$ *Insert*

10. $u_{j+1} = u_j + n^{-1}$ *Increment threshold*

11. **Return** S'

Also called **stochastic universal sampling**

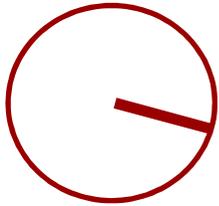

Mobile Robot Localization

- Each particle is a potential pose of the robot
- Proposal distribution is the motion model of the robot (prediction step)
- The observation model is used to compute the importance weight (correction step)

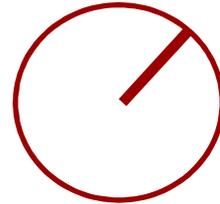

[For details, see PDF file on the lecture web page]

Motion Model Reminder

start pose

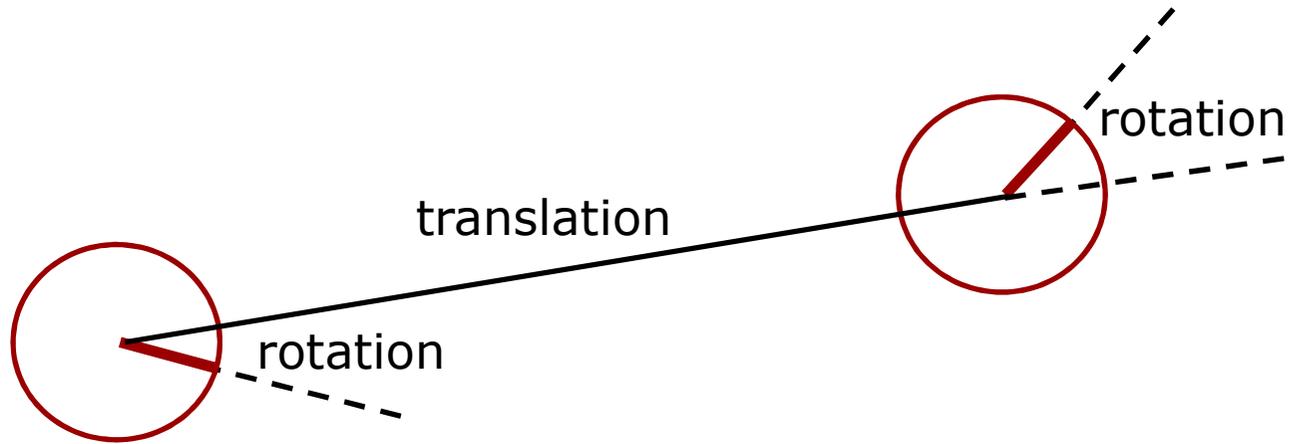

end pose

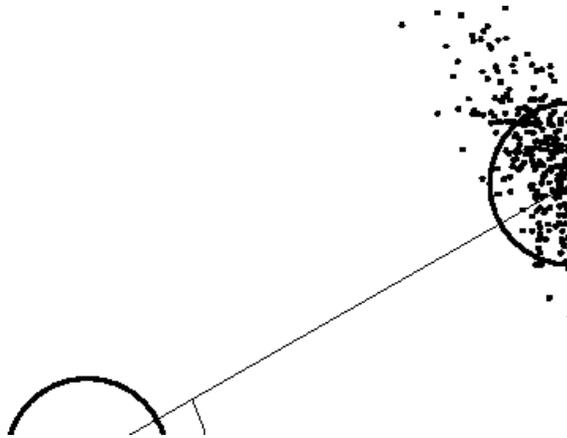

According to the estimated motion

Motion Model Reminder

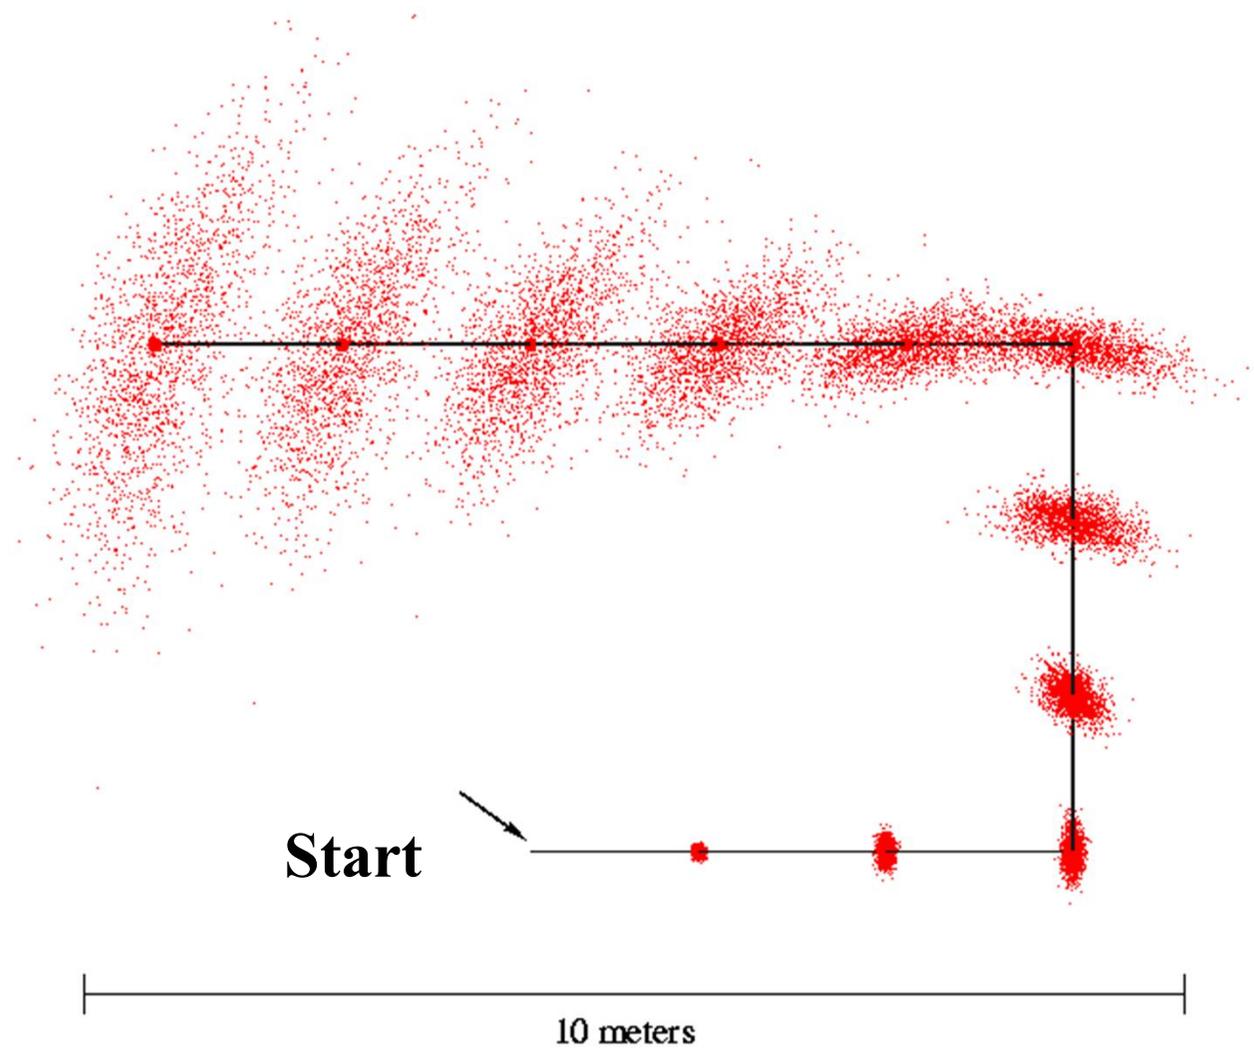

- Decompose the motion into
 - Traveled distance
 - Start rotation
 - End rotation

Motion Model Reminder

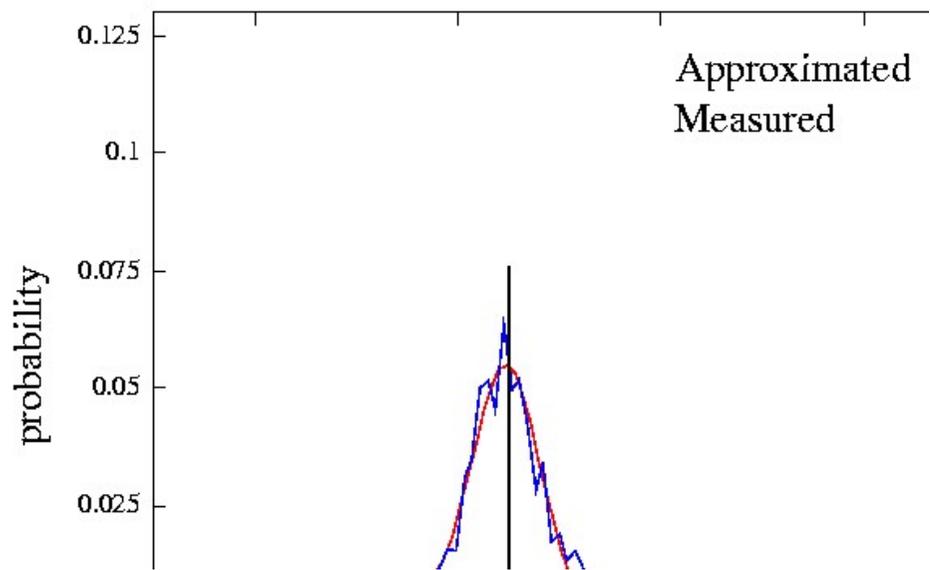

- Uncertainty in the translation of the robot:
Gaussian over the traveled distance
- Uncertainty in the rotation of the robot:
Gaussians over start and end rotation
- For each particle, draw a new pose by sampling from these three individual normal distributions

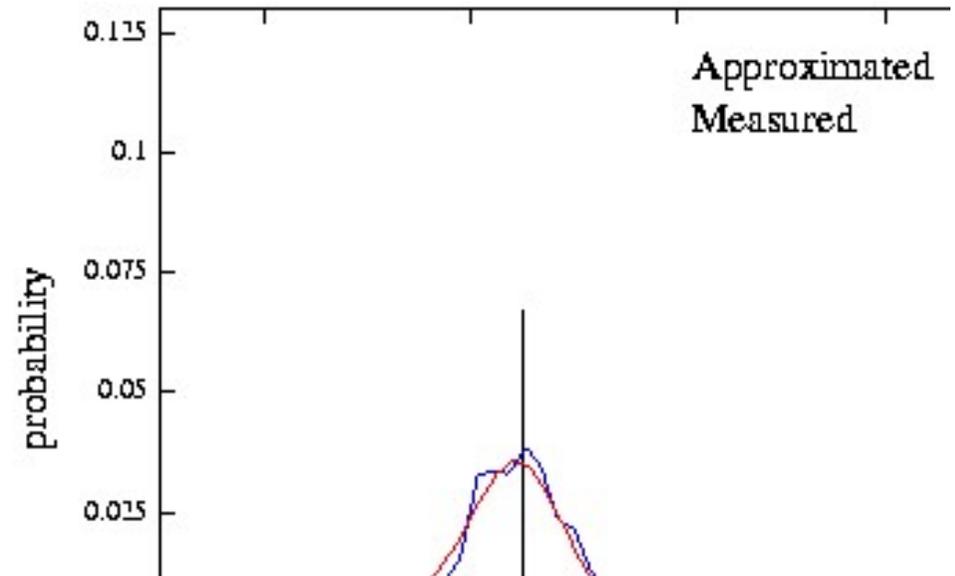

Motion Model Reminder

Proximity Sensor Model Reminder

Laser sensor

Sonar sensor

Mobile Robot Localization Using Particle Filters (1)

- Each particle is a potential pose of the robot
- The set of weighted particles approximates the posterior belief about the robot's pose (target distribution)

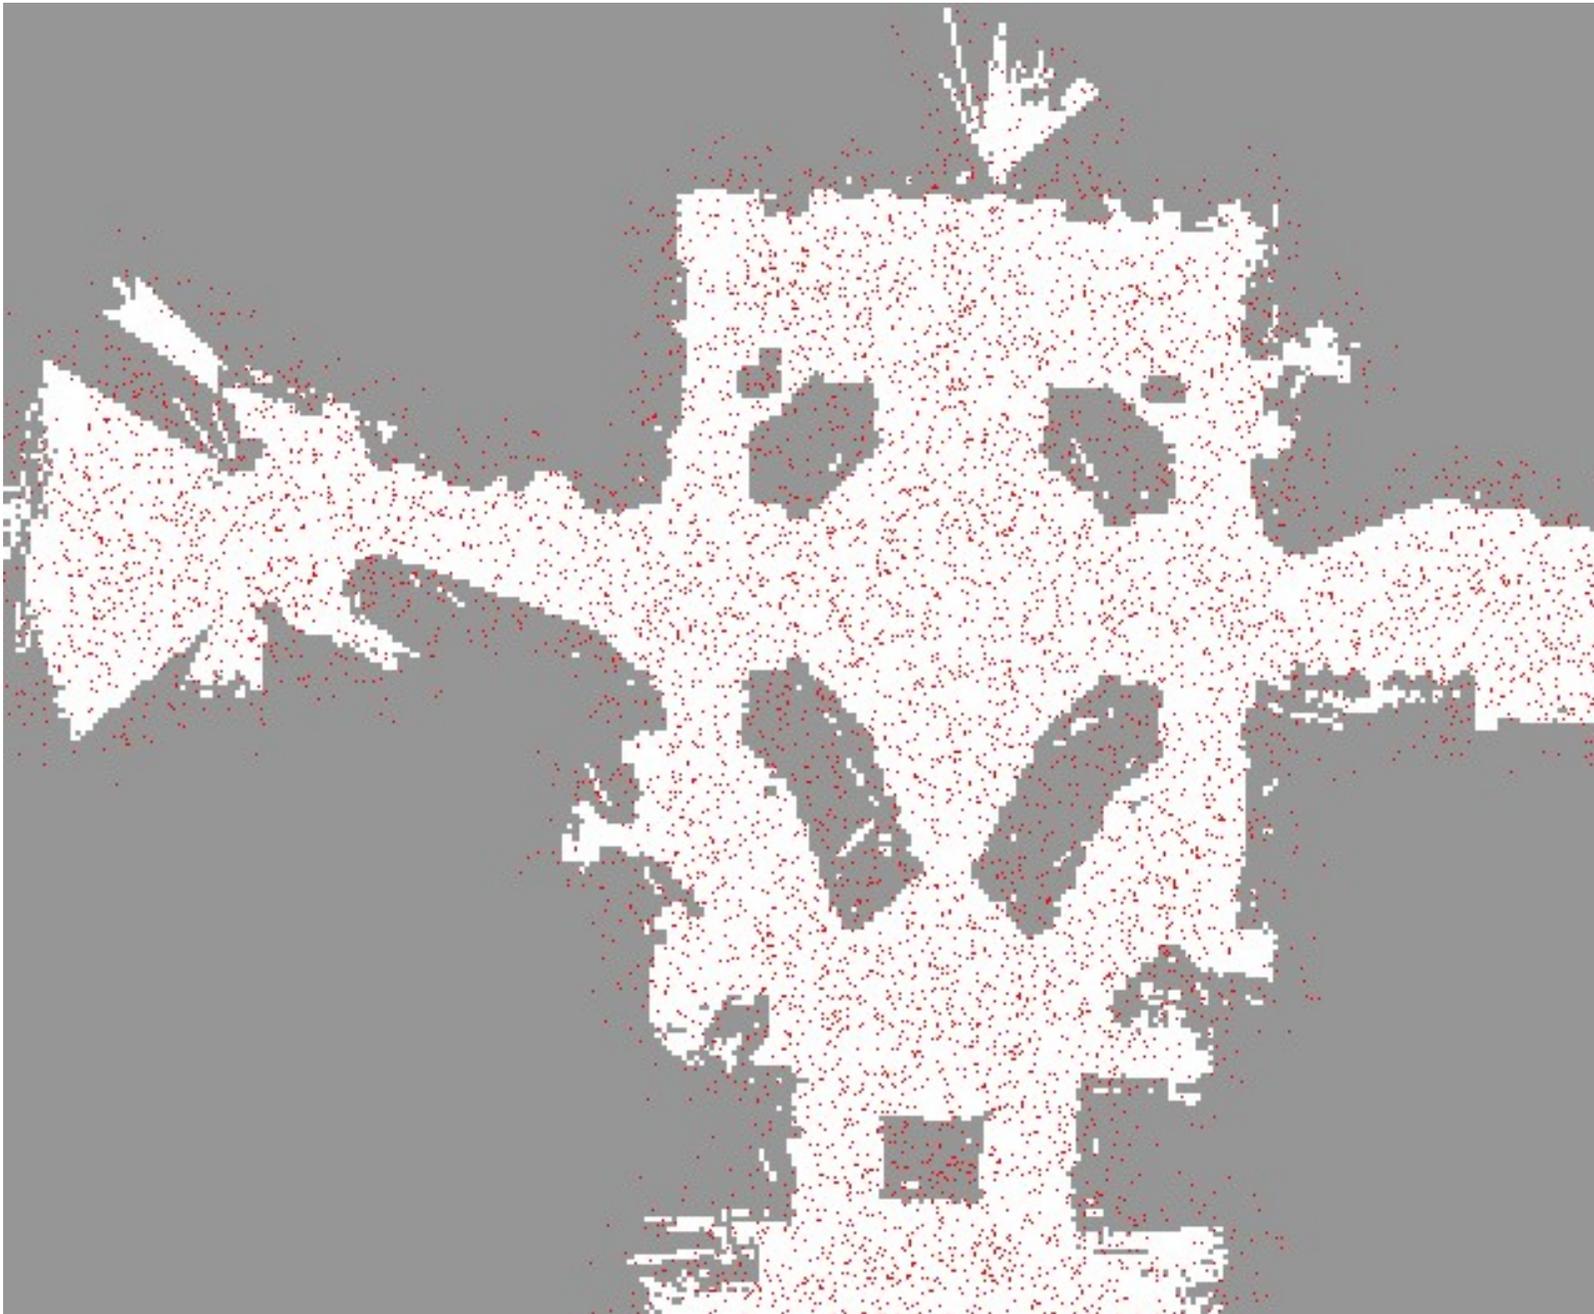

Mobile Robot Localization Using Particle Filters (2)

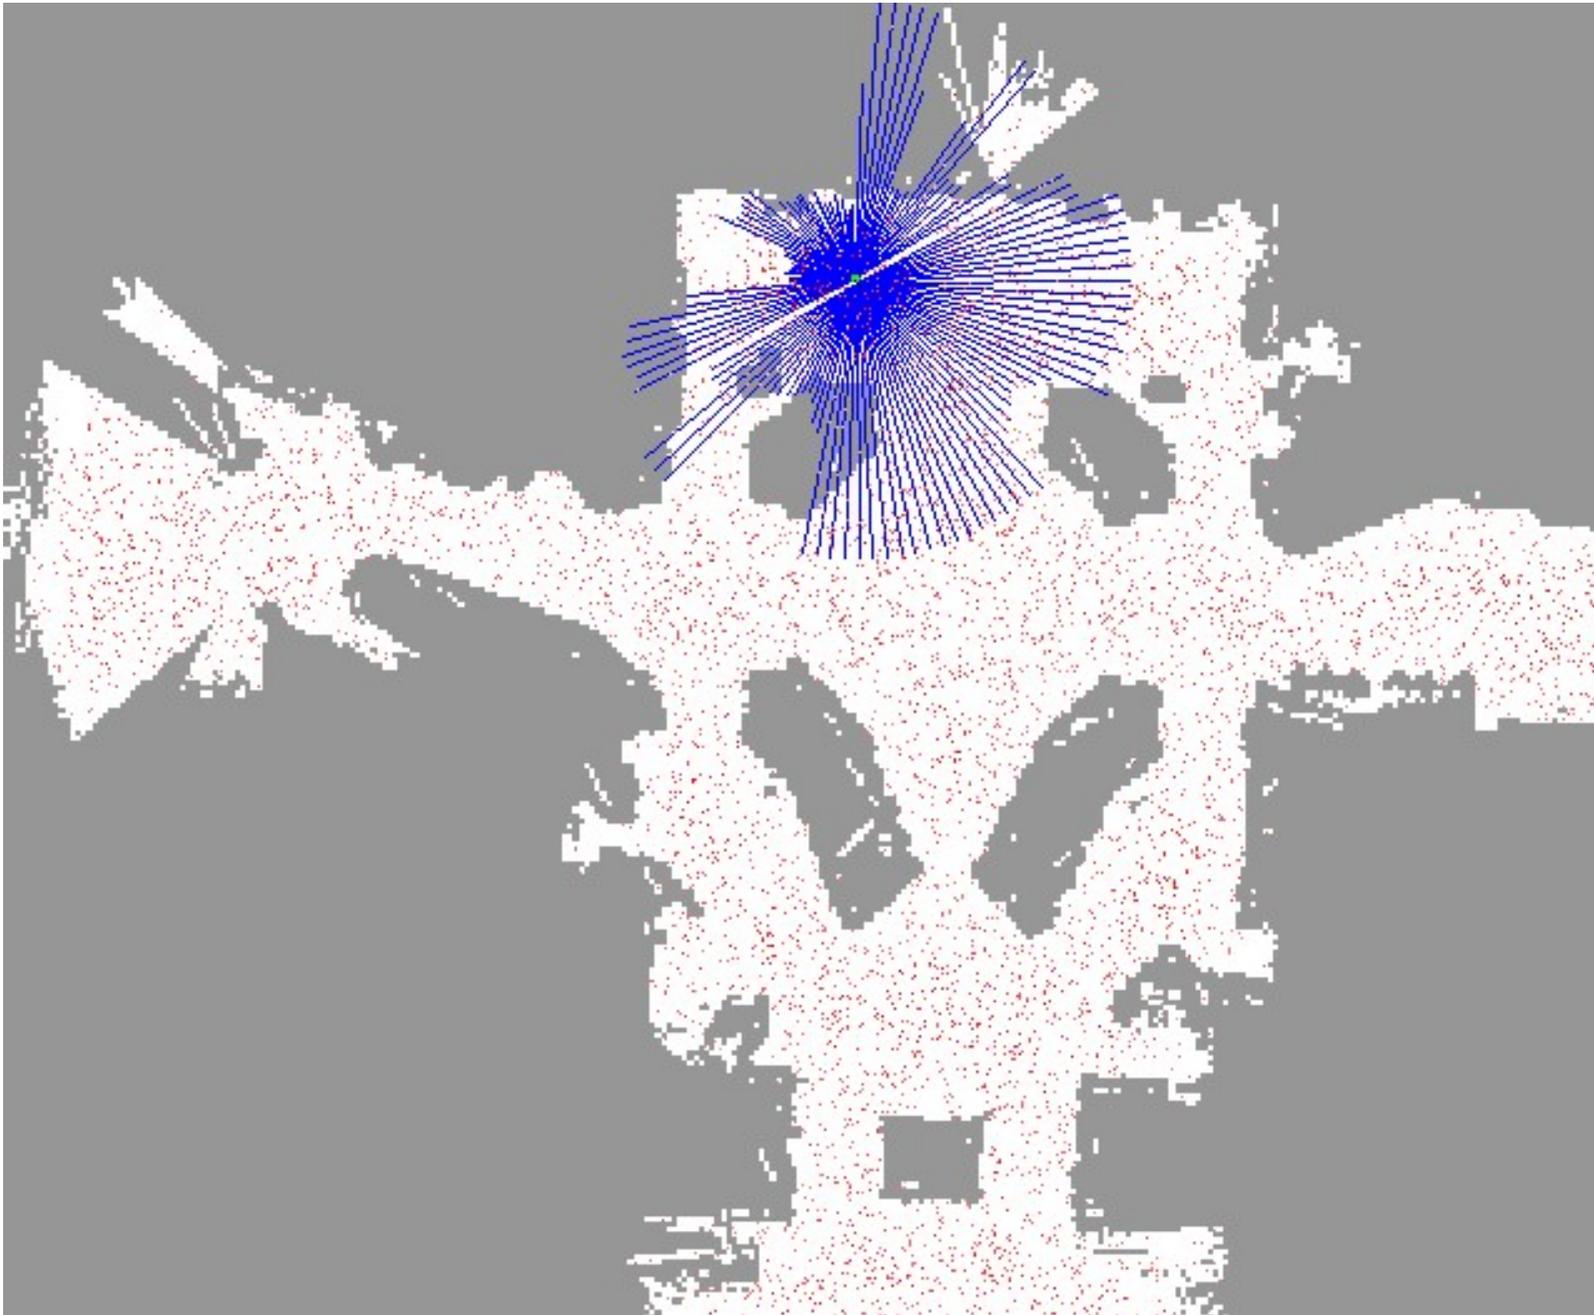

- Particles are drawn from the motion model (proposal distribution)
- Particles are weighted according to the observation model (sensor model)
- Particles are resampled according to the particle weights

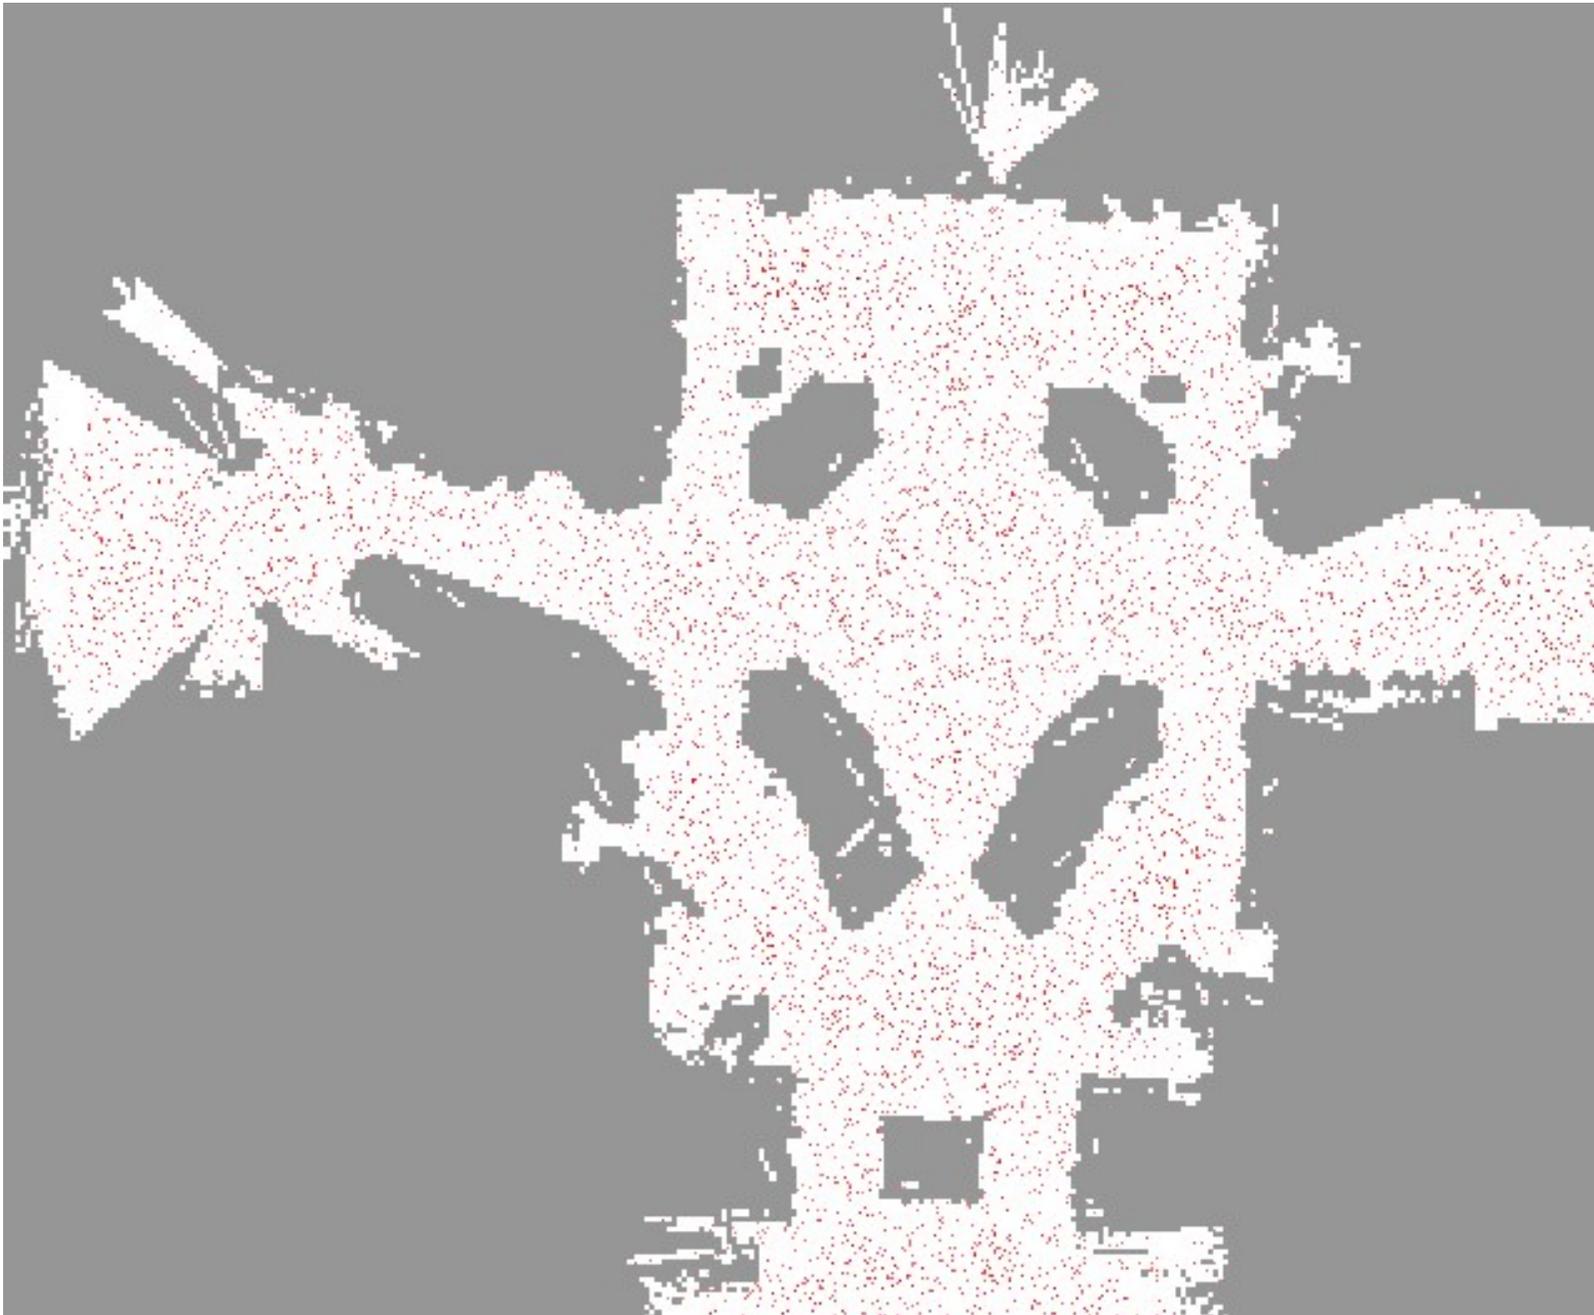

Mobile Robot Localization Using Particle Filters (3)

Why is resampling needed?

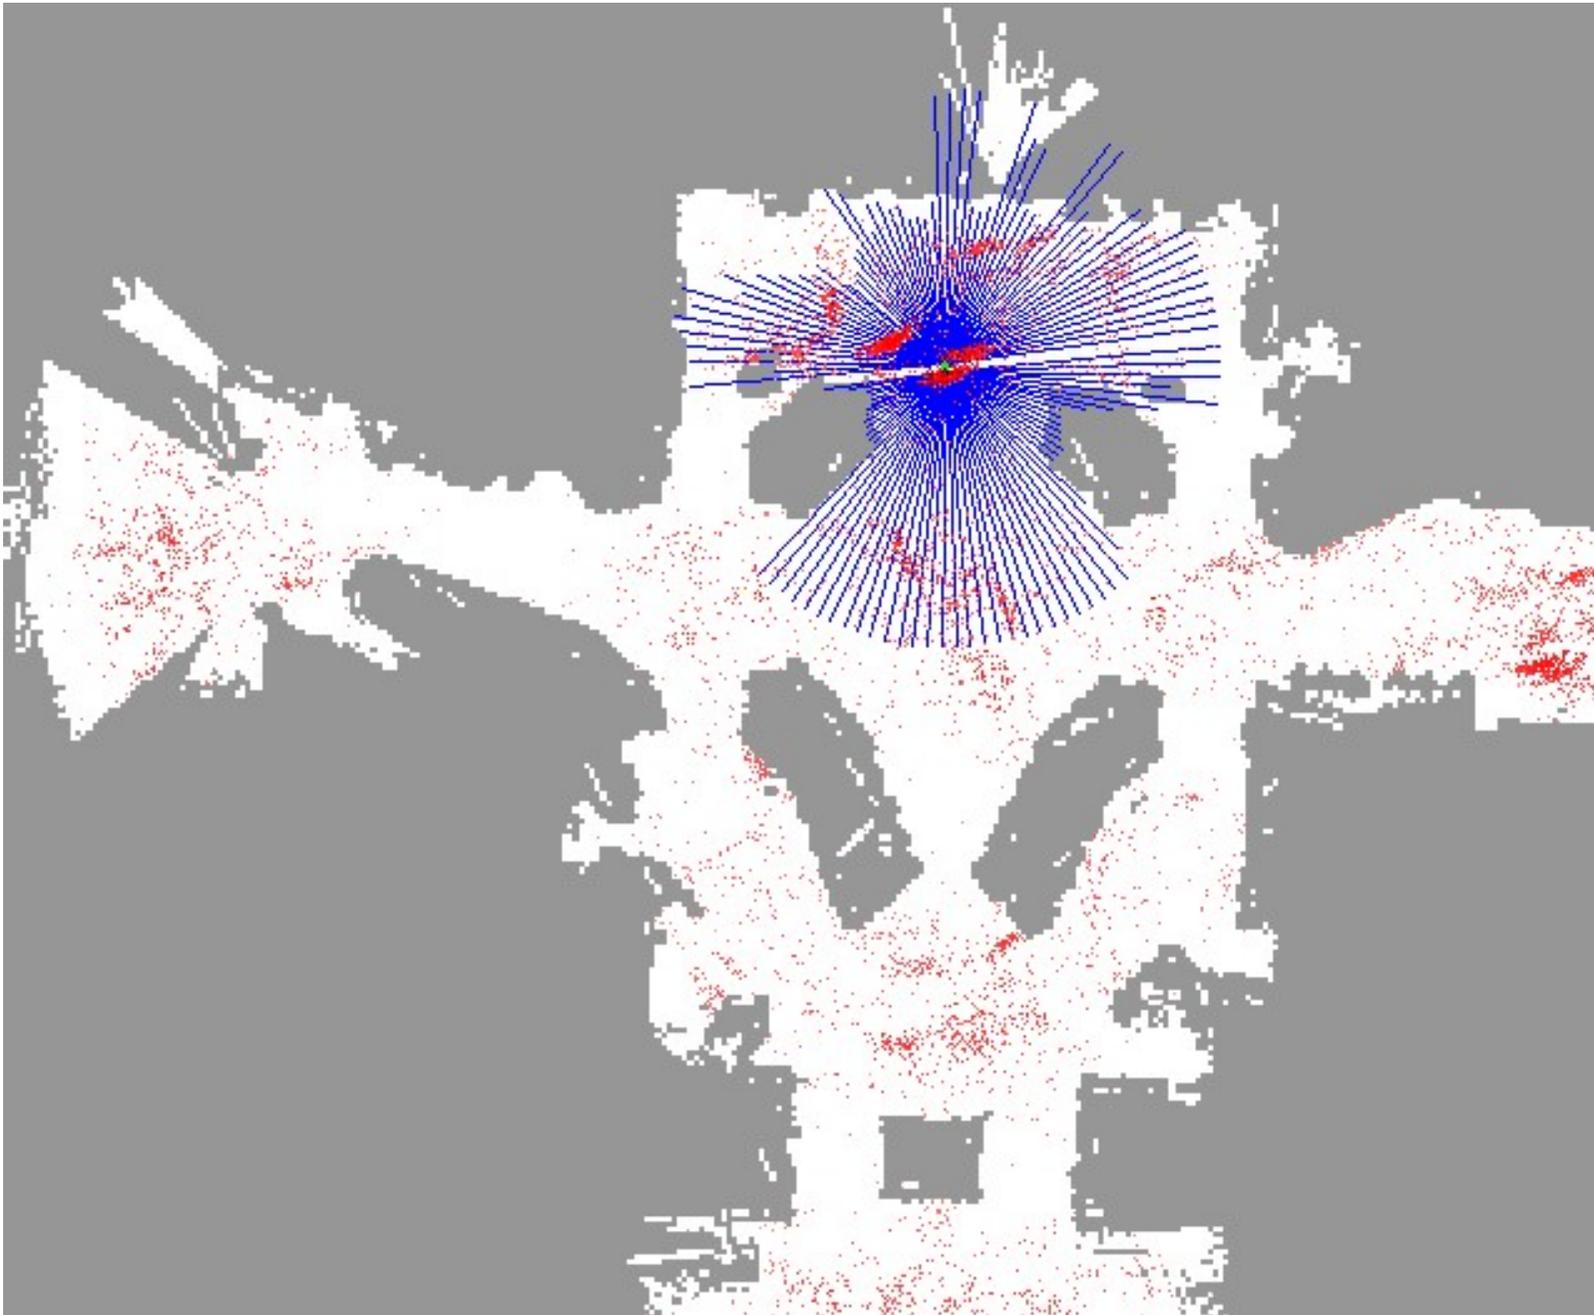

- We only have a finite number of particles
- Without resampling: The filter is likely to lose track of the “good” hypotheses
- Resampling ensures that particles stay in the meaningful area of the state space

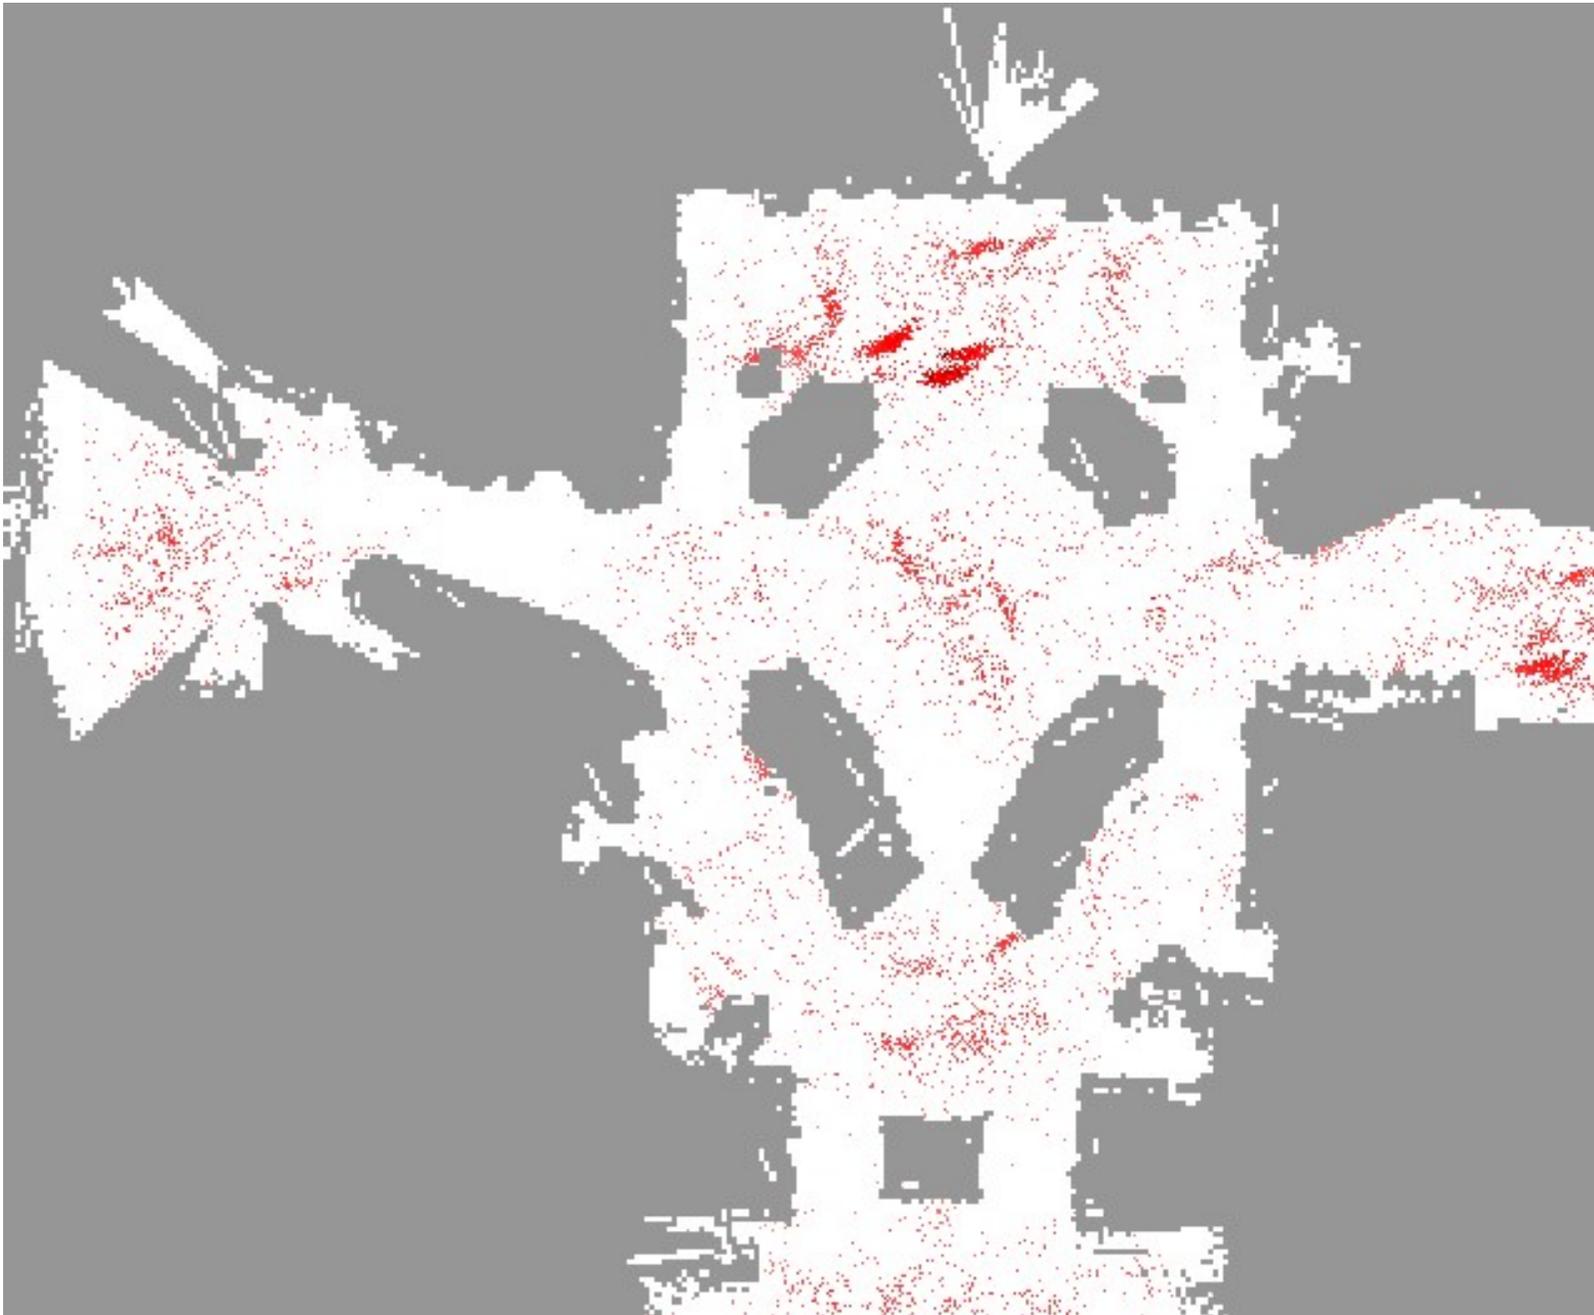

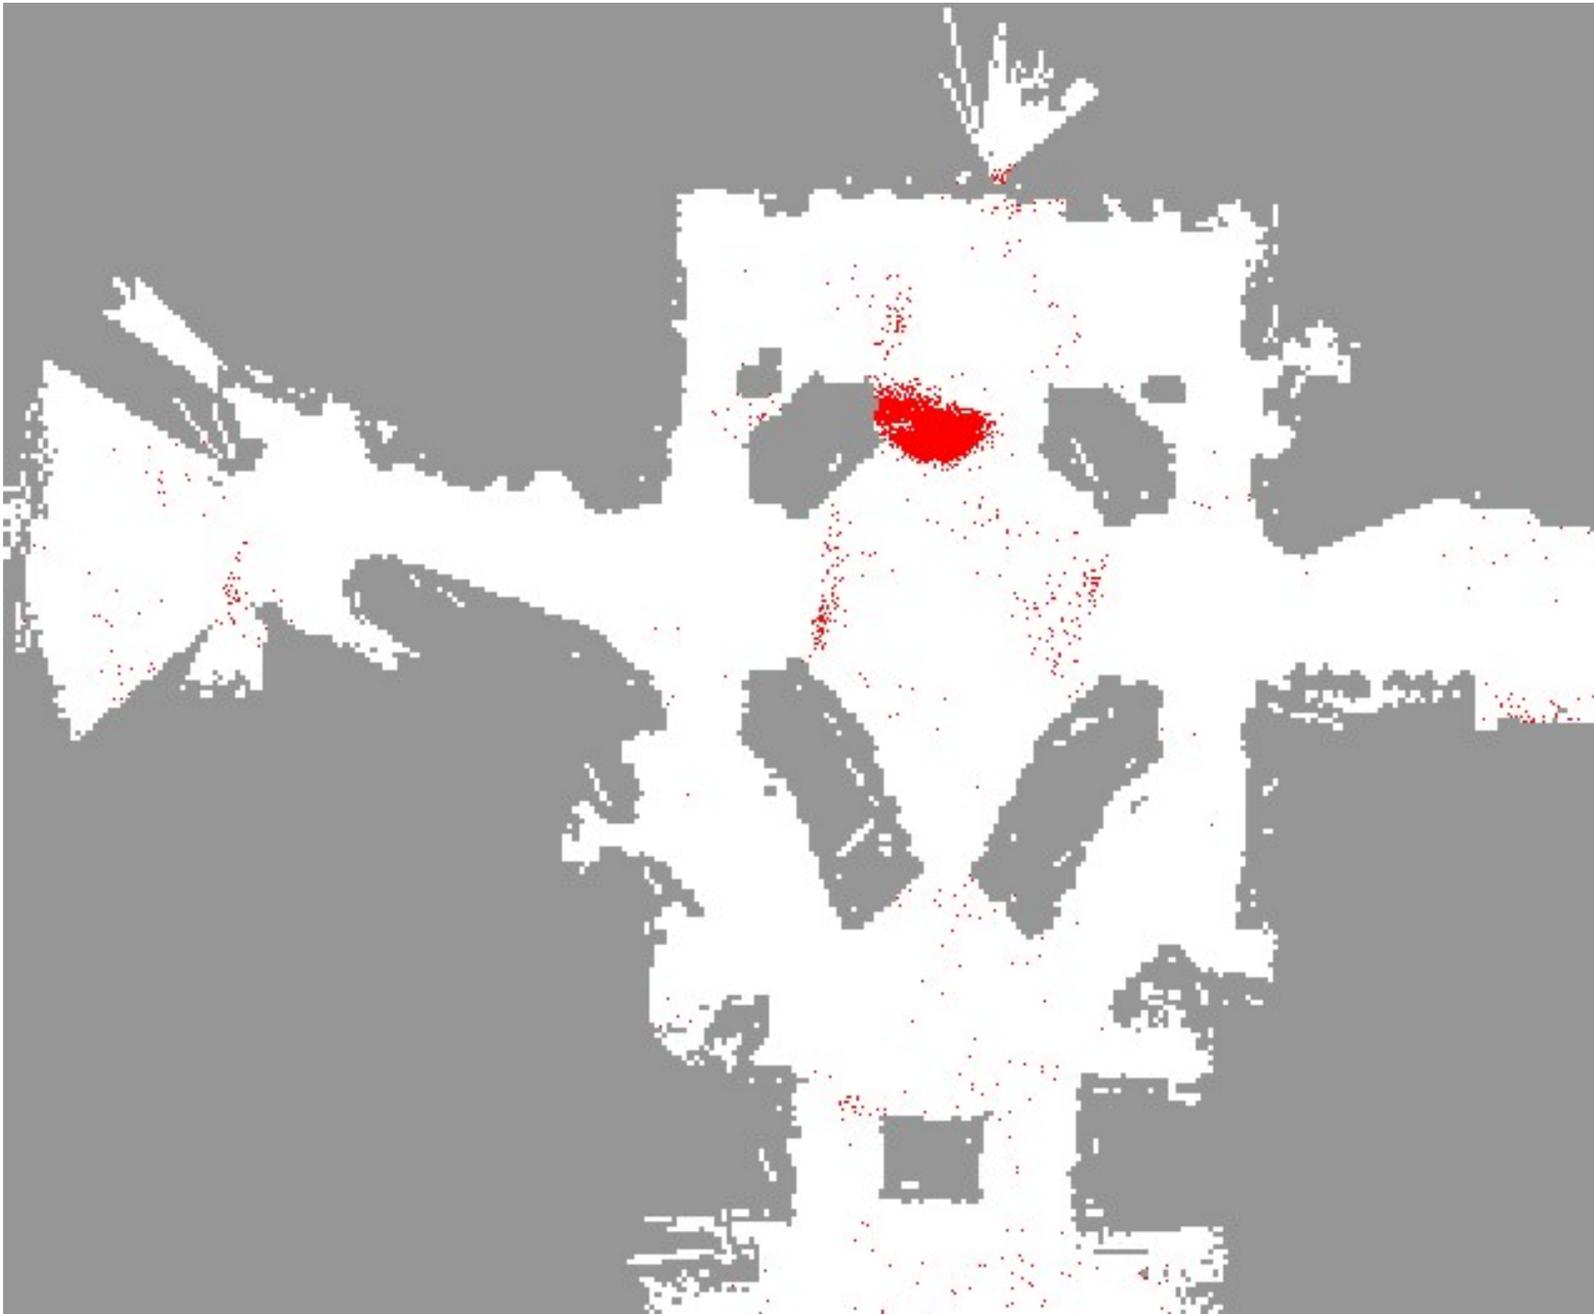

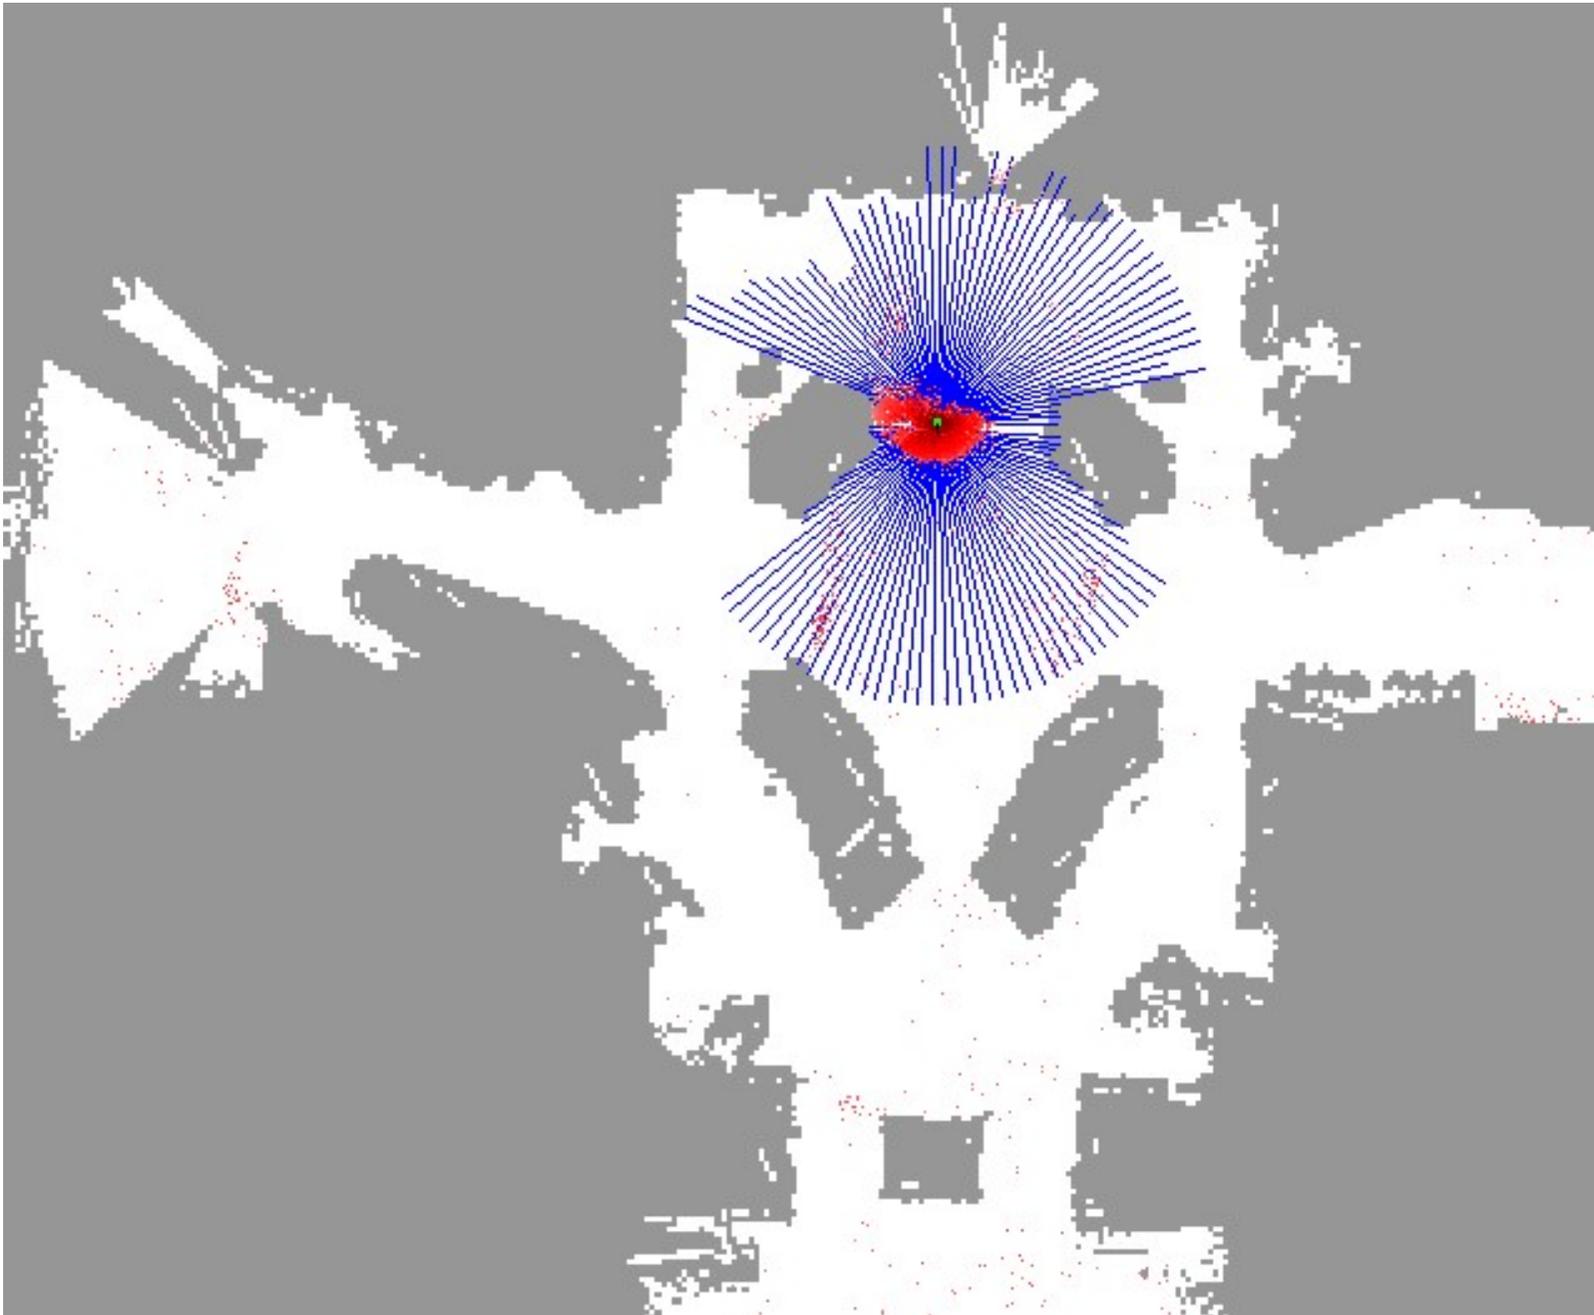

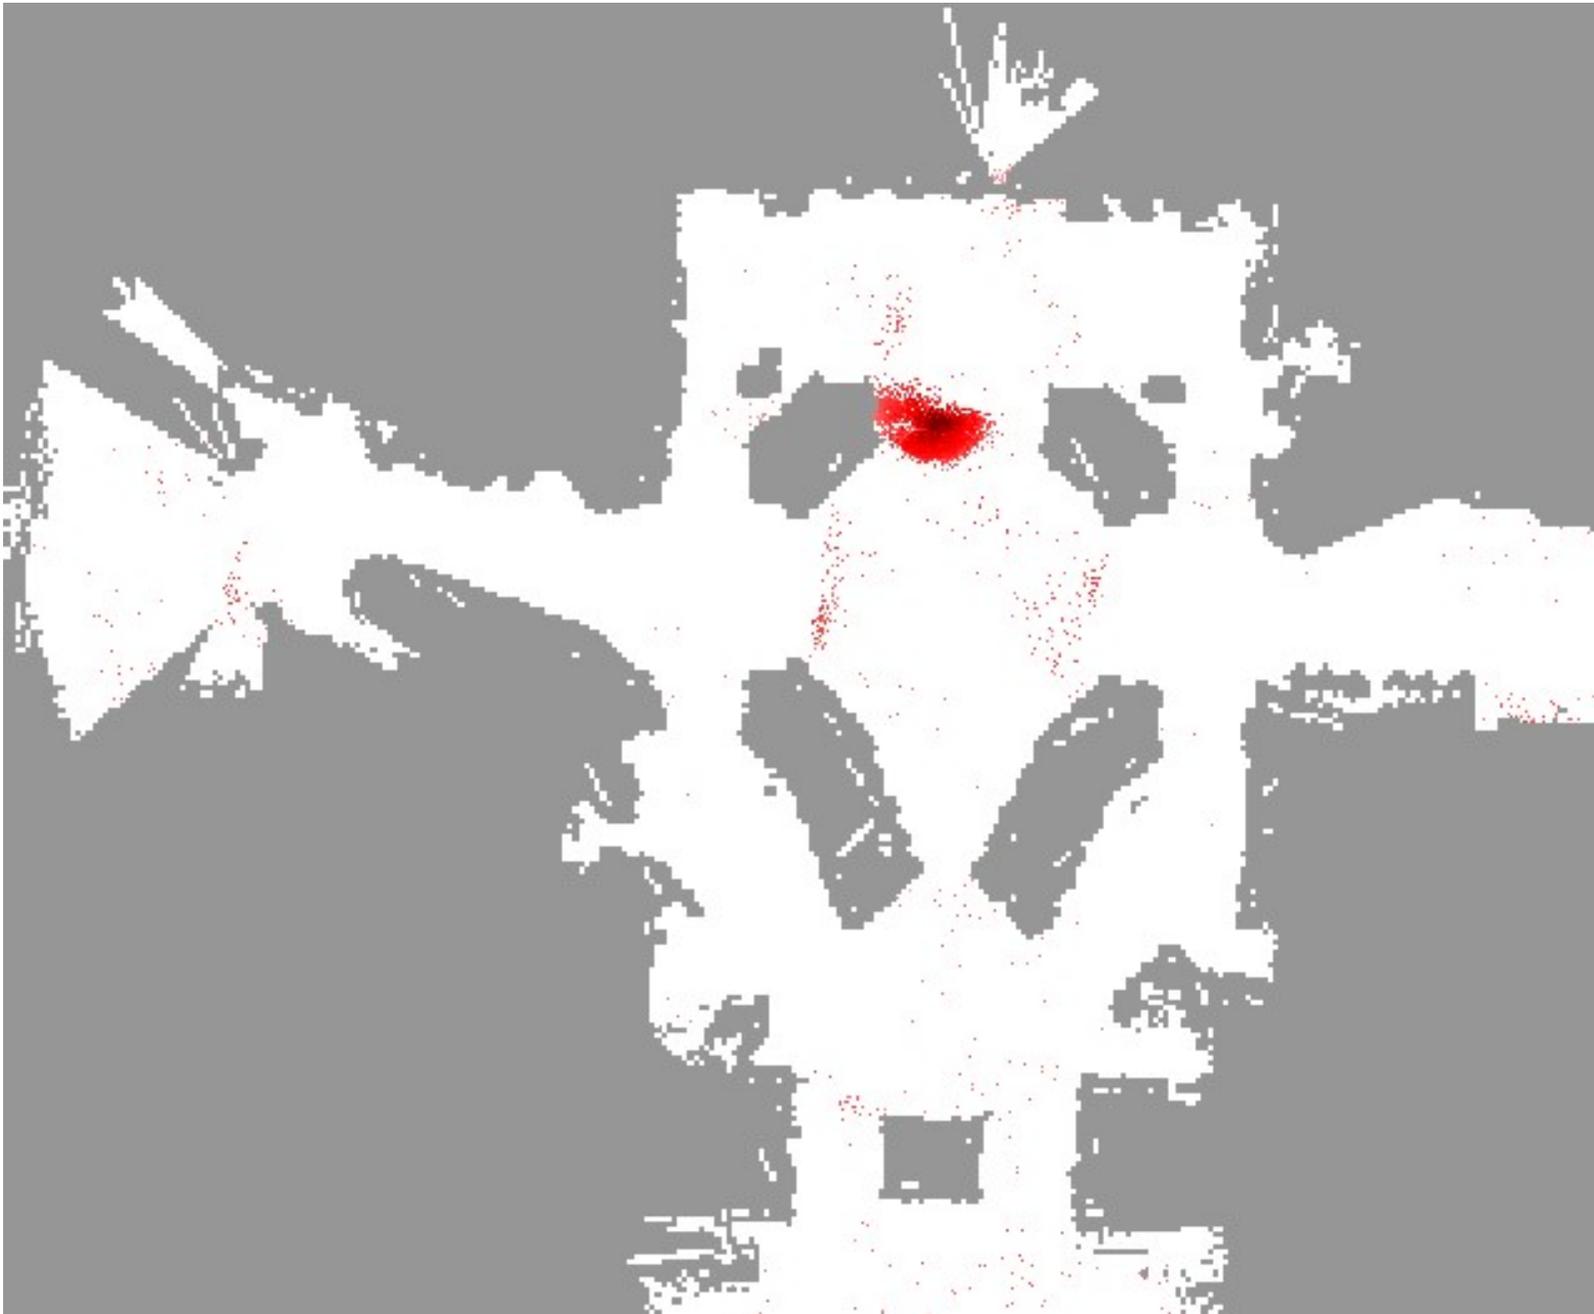

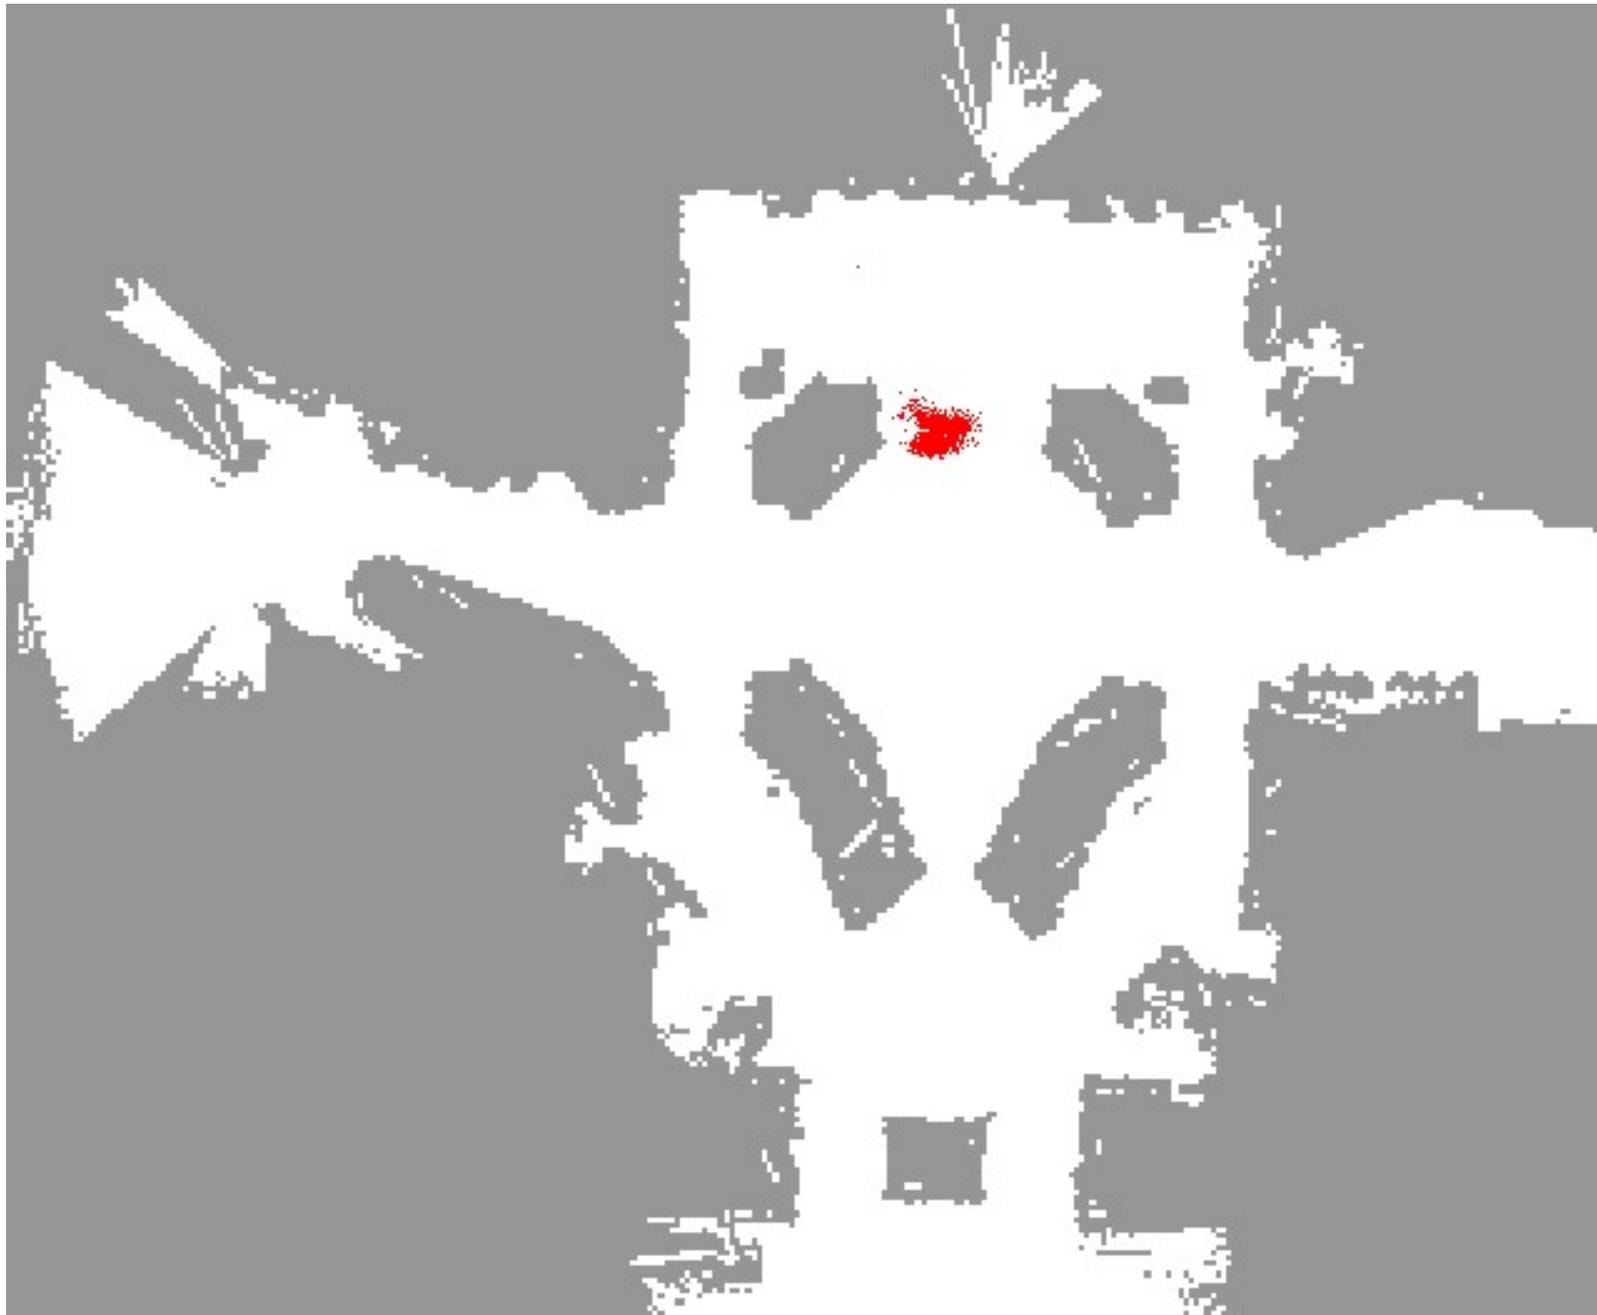

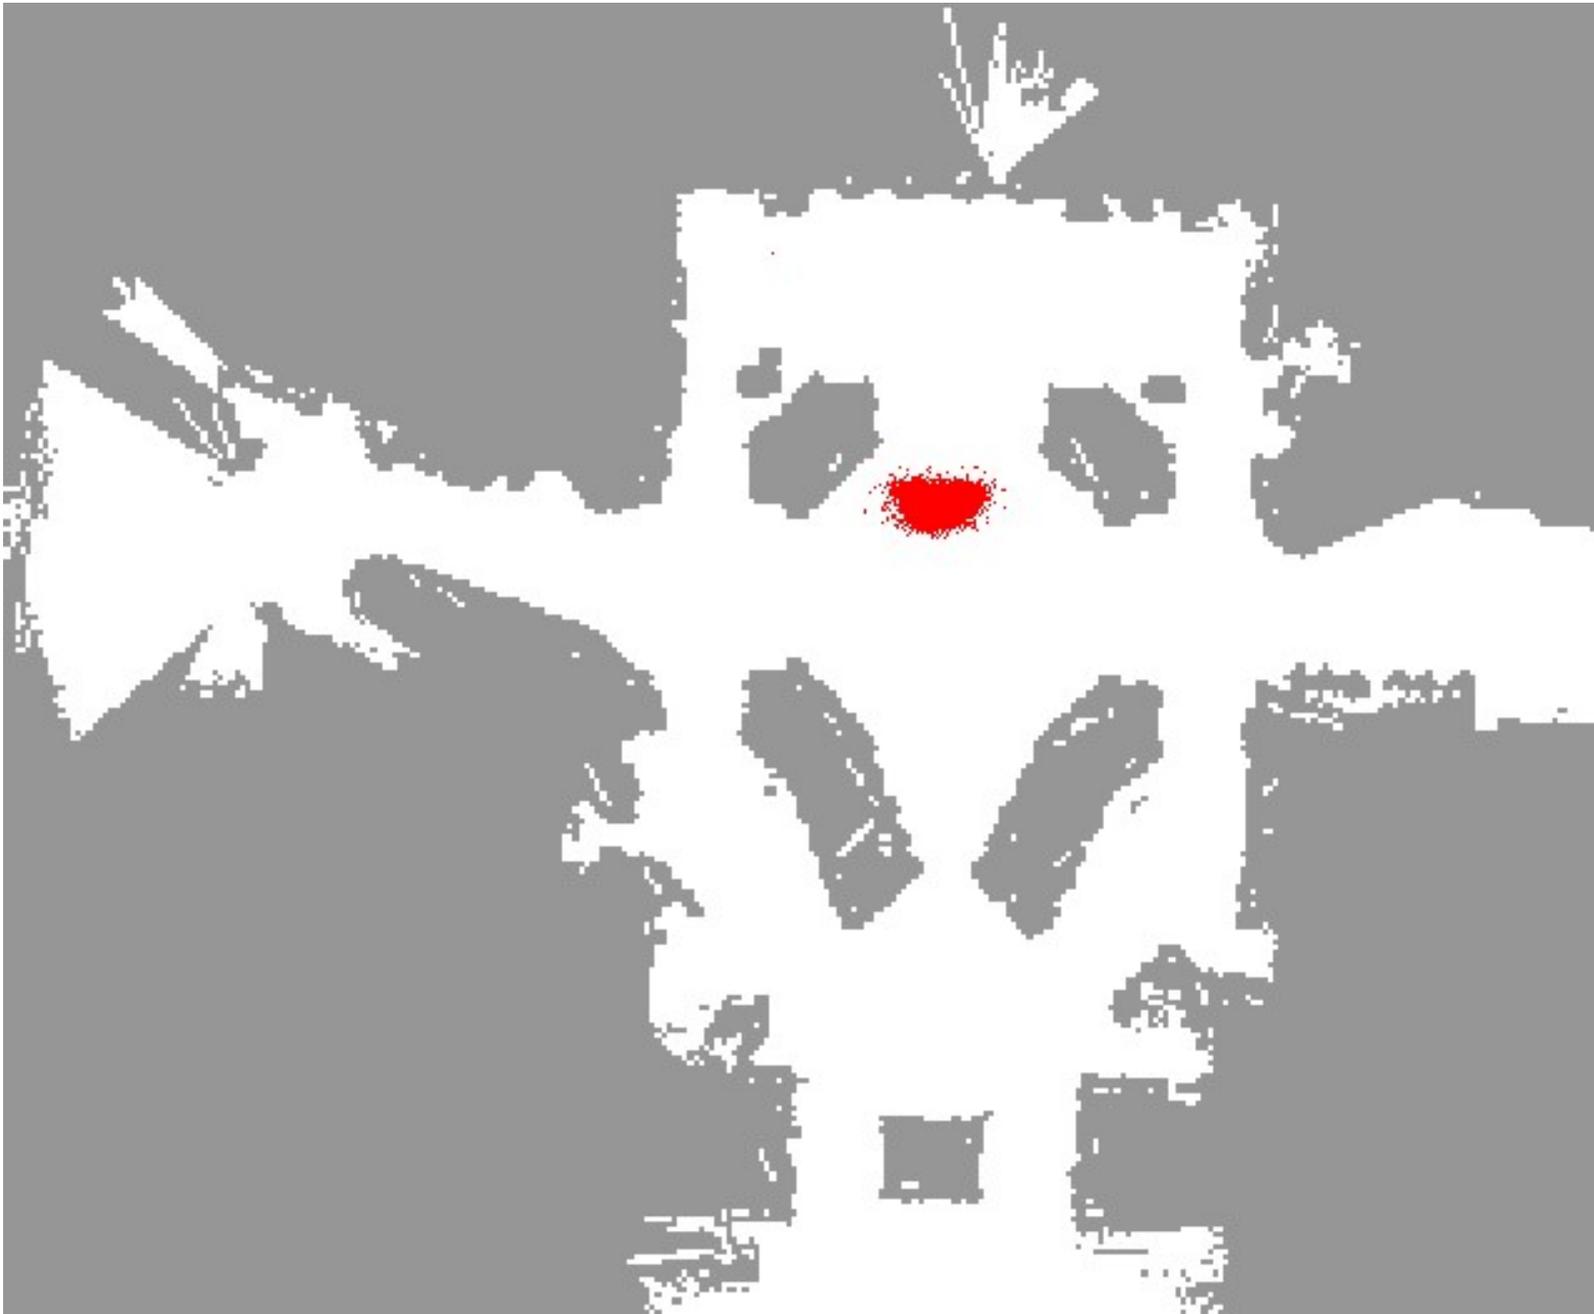

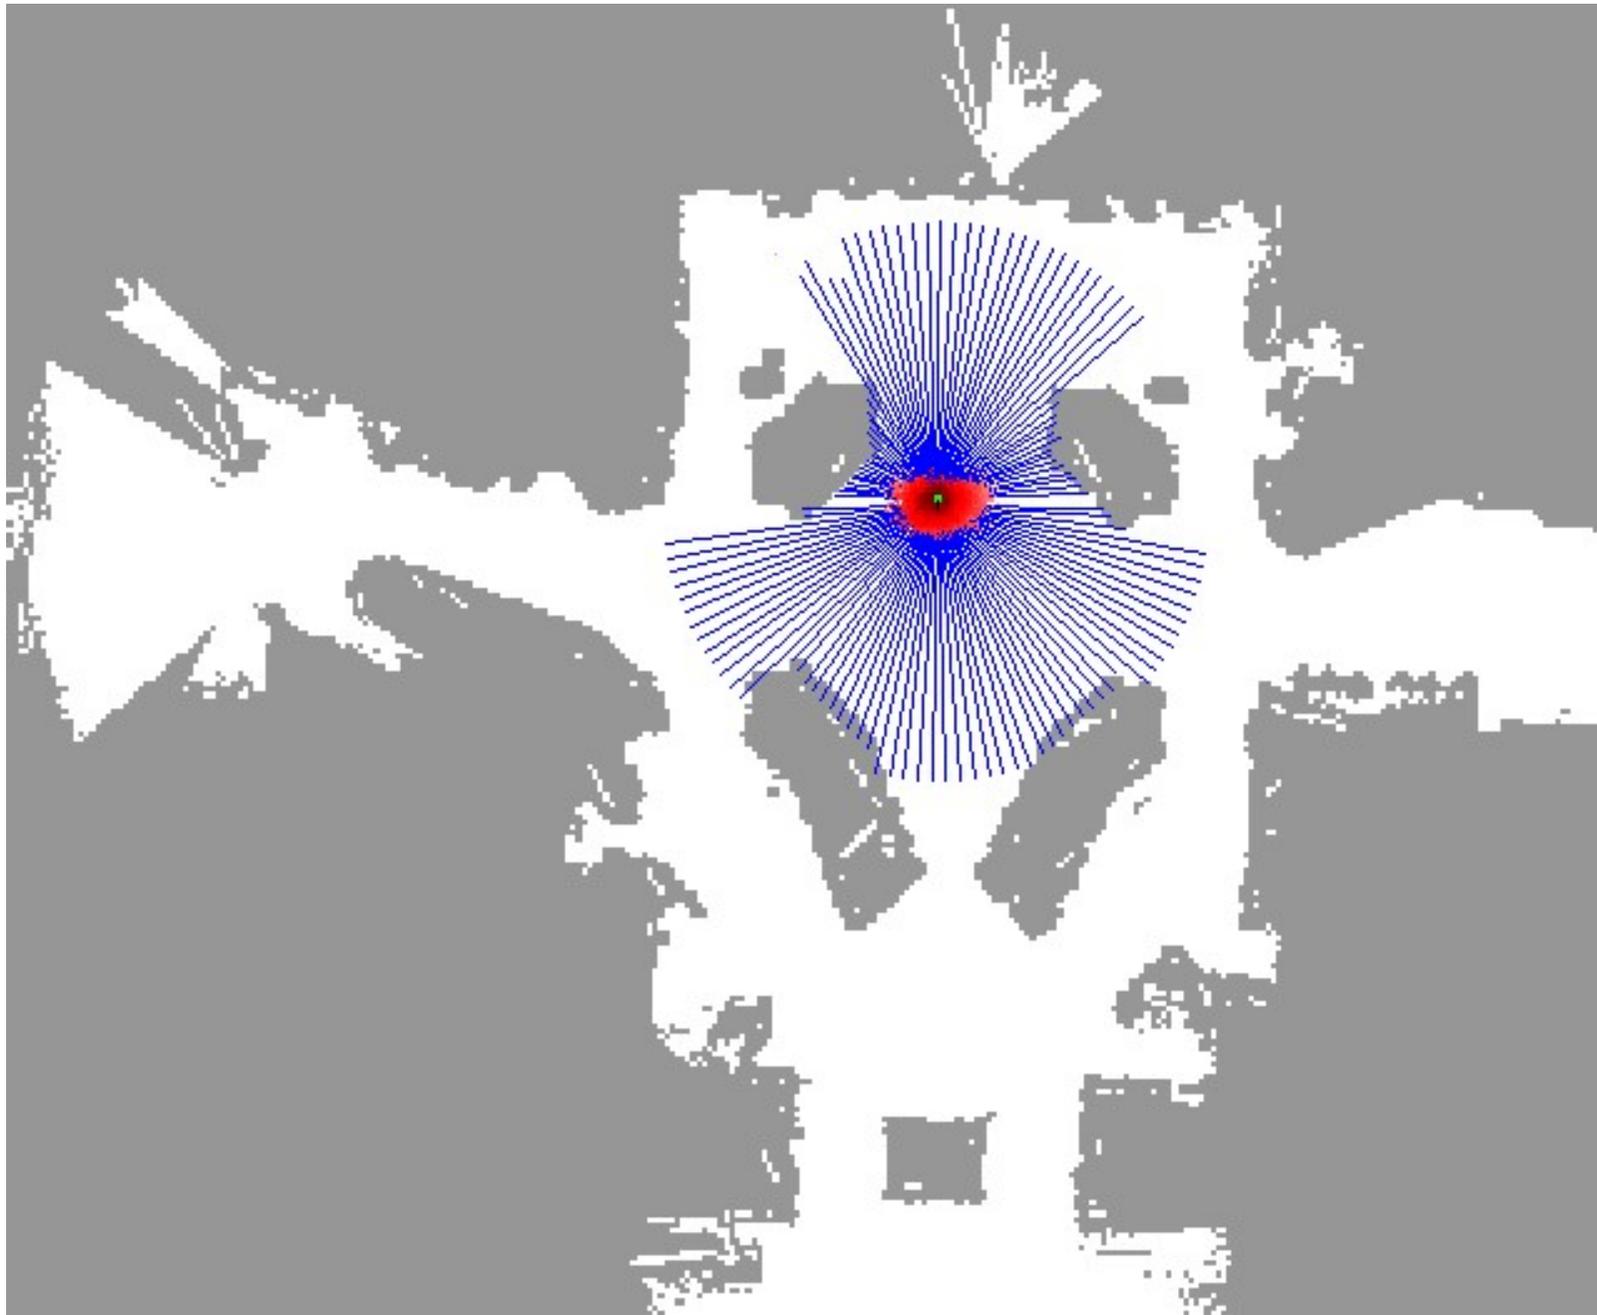

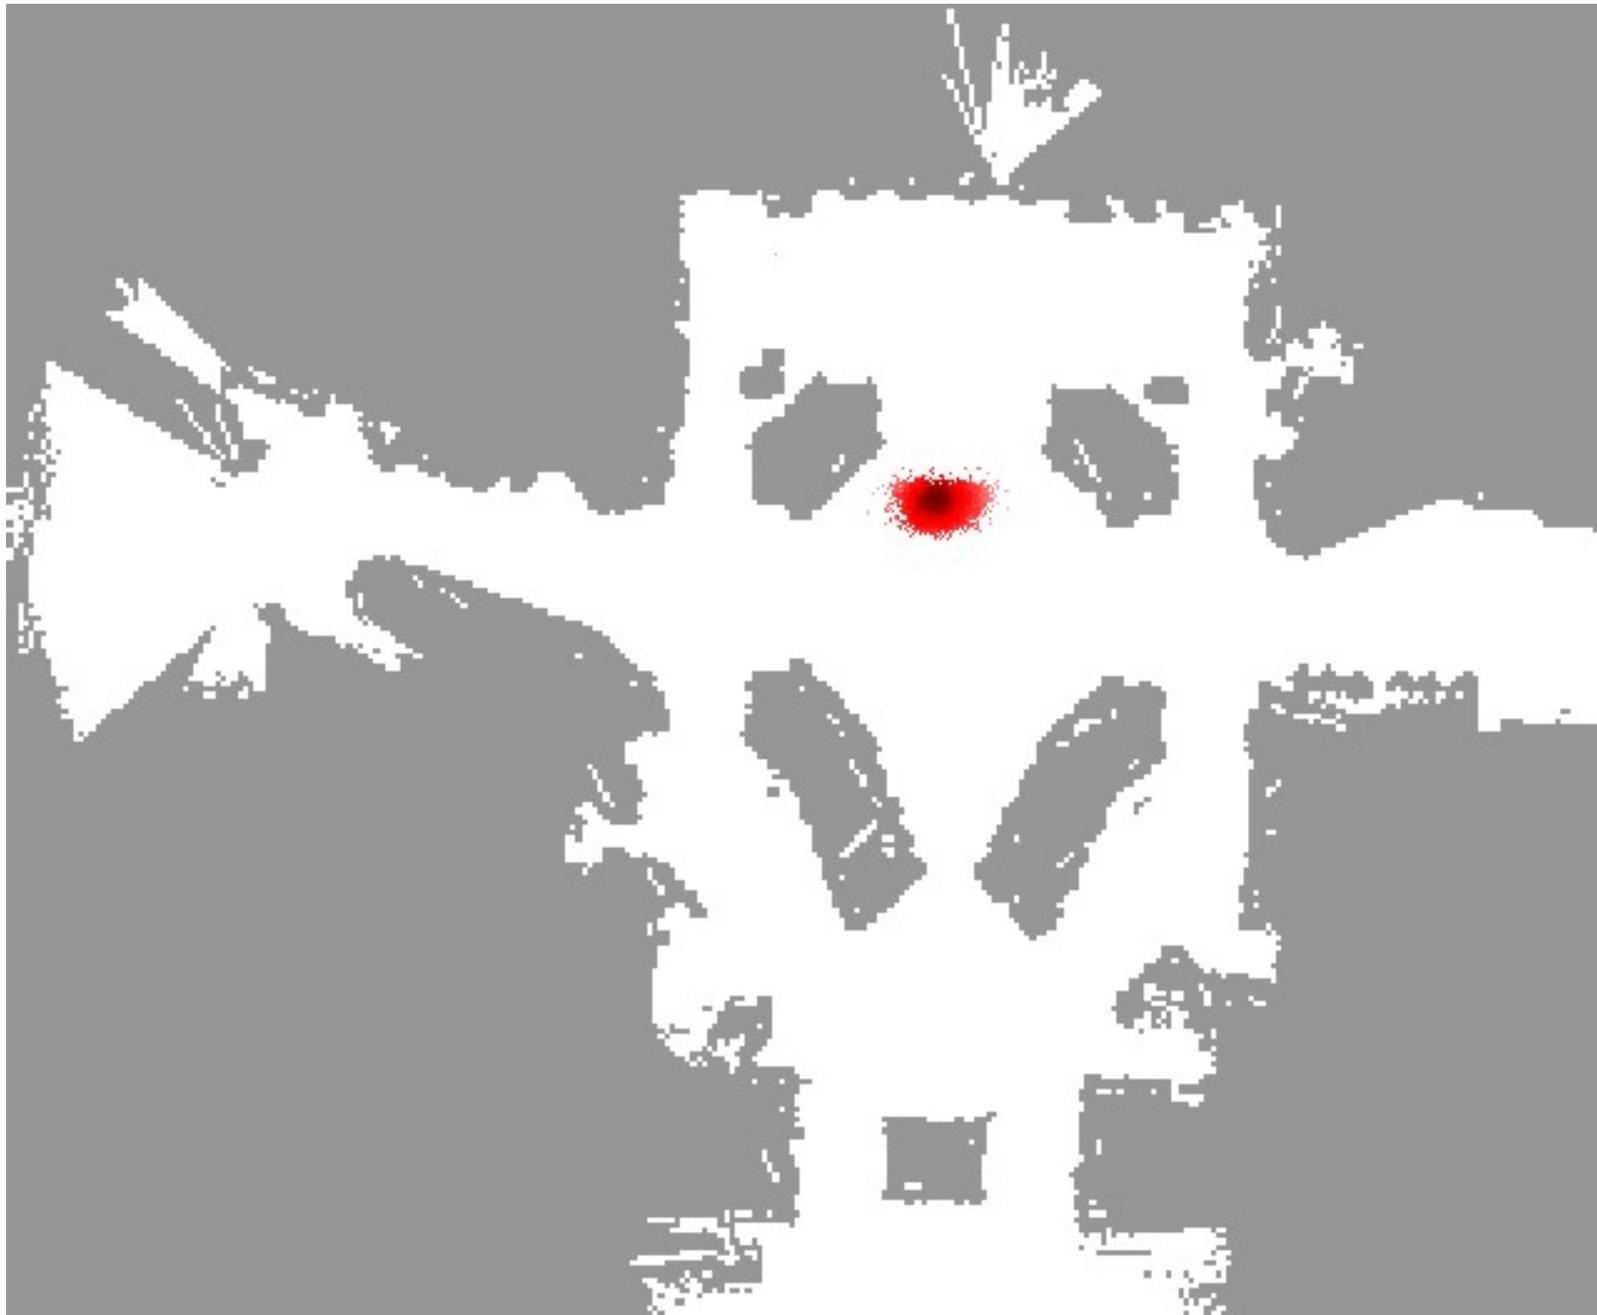

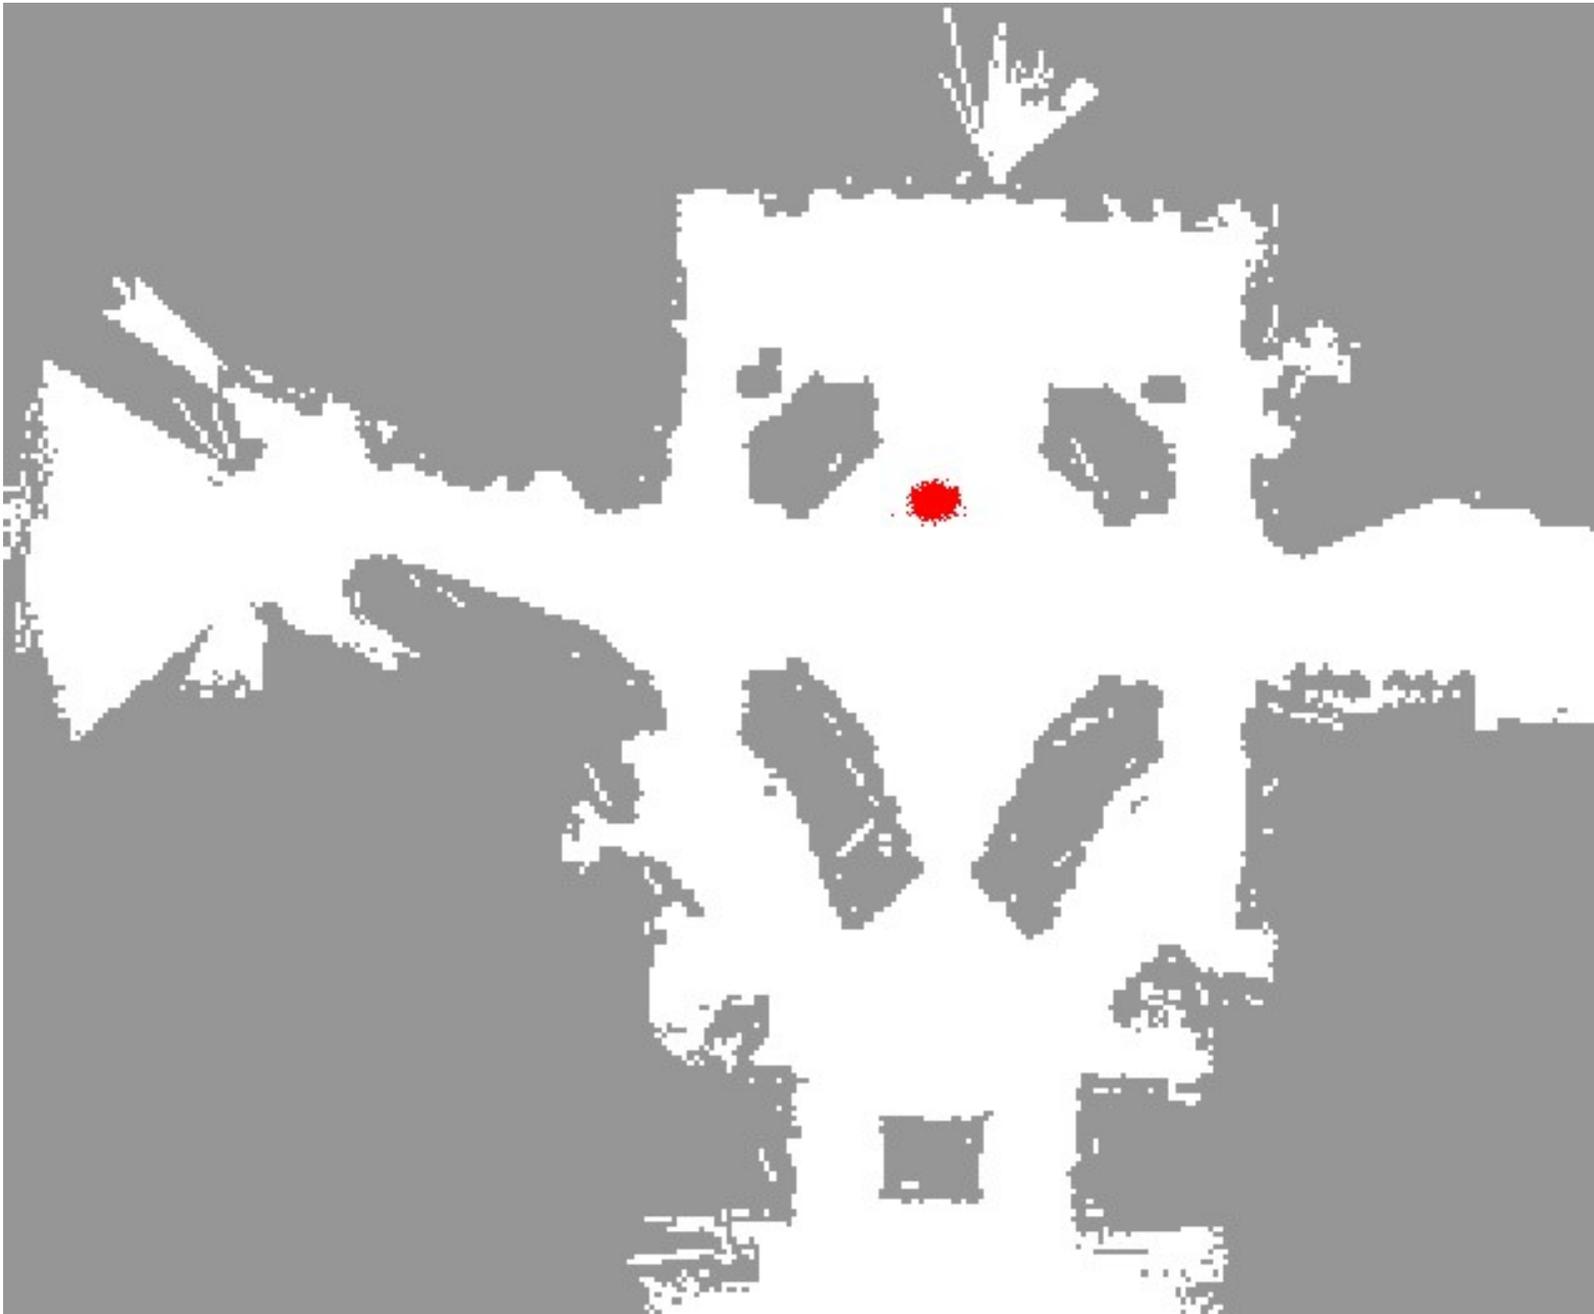

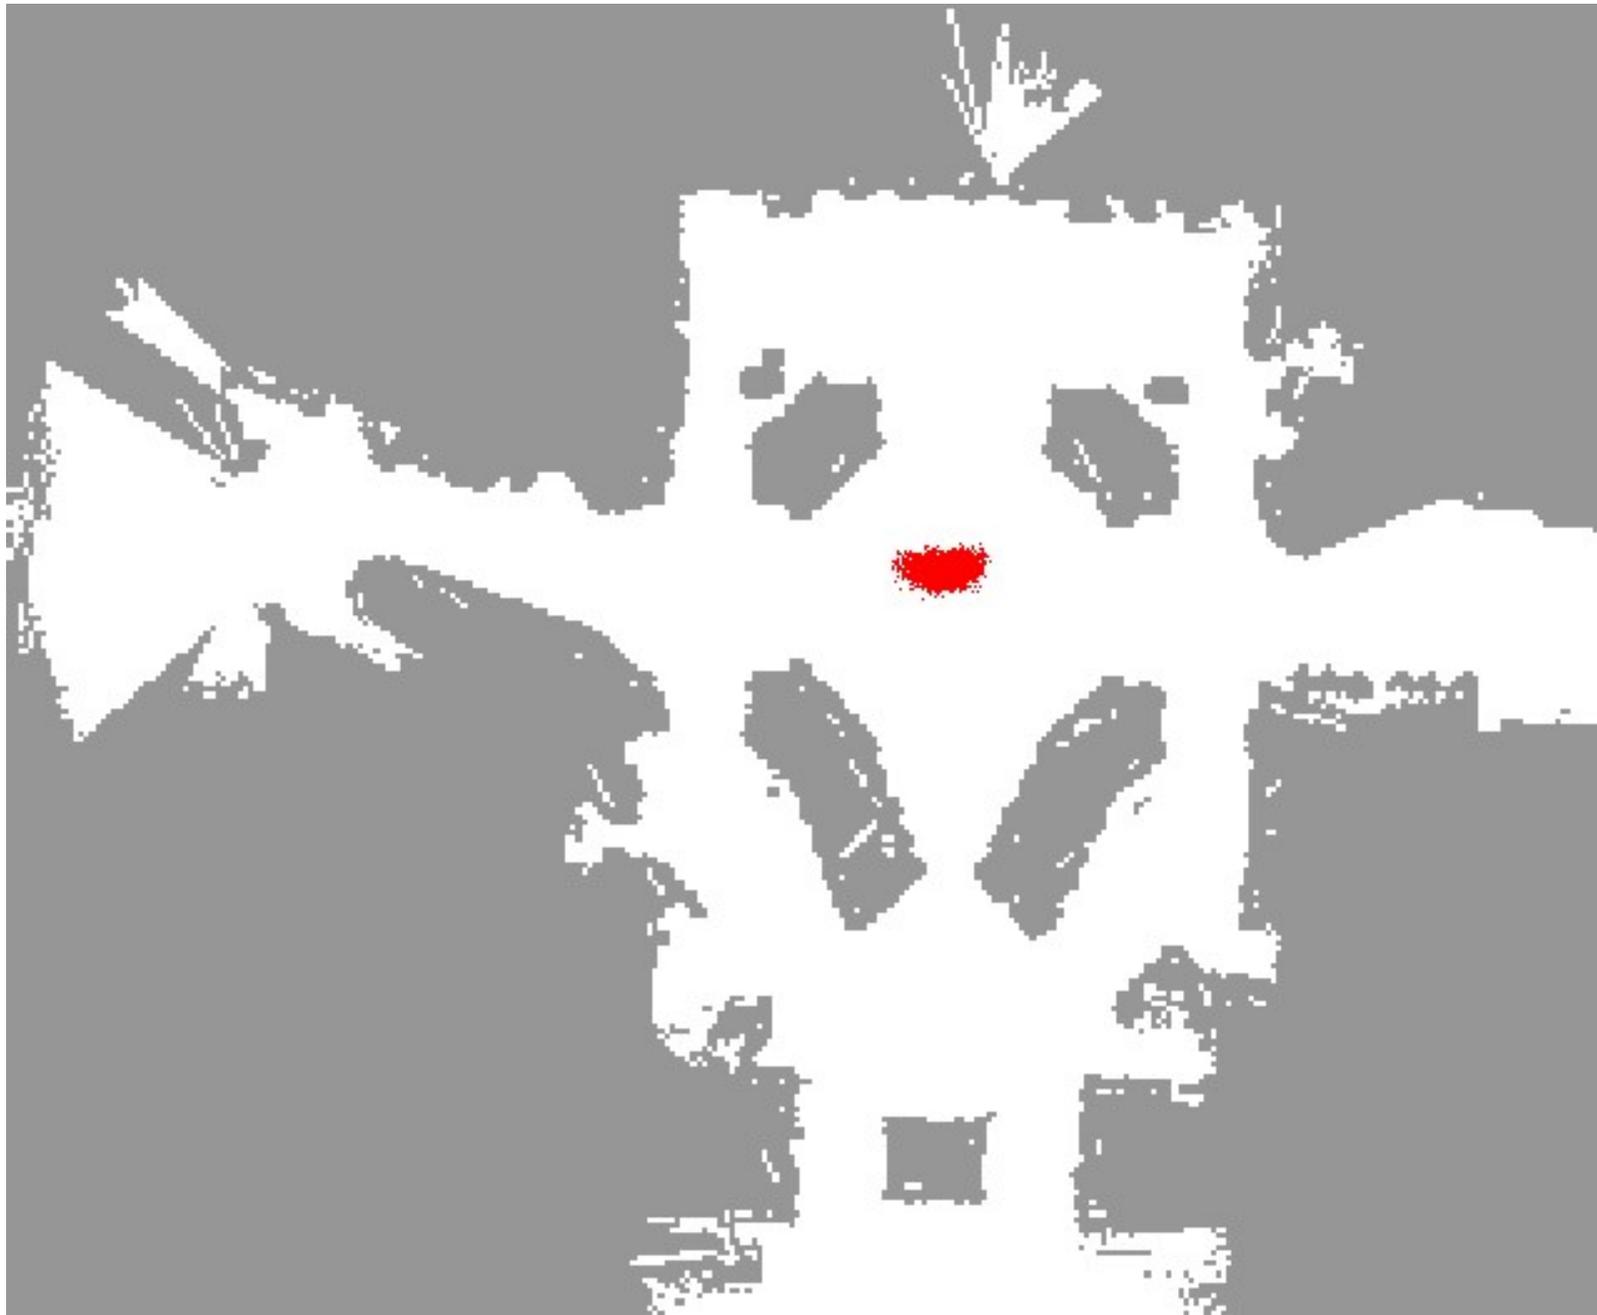

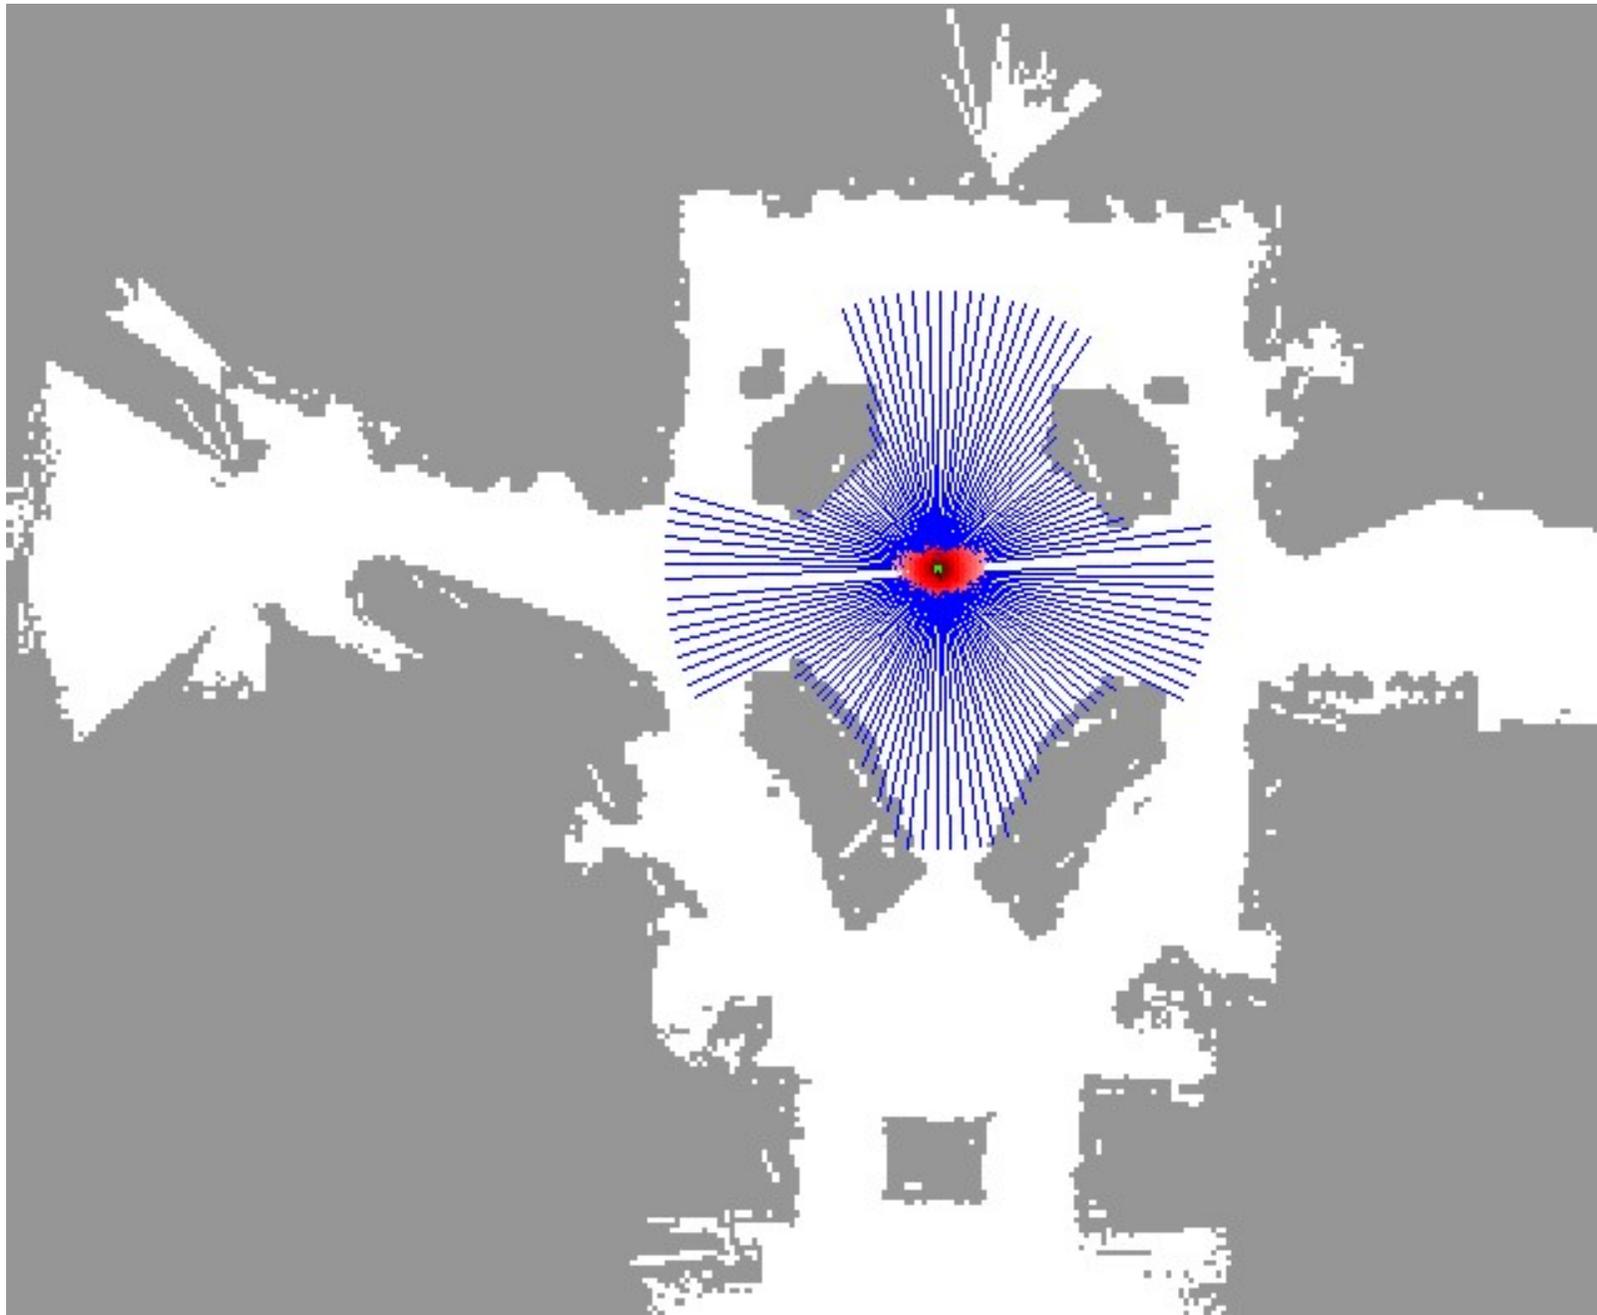

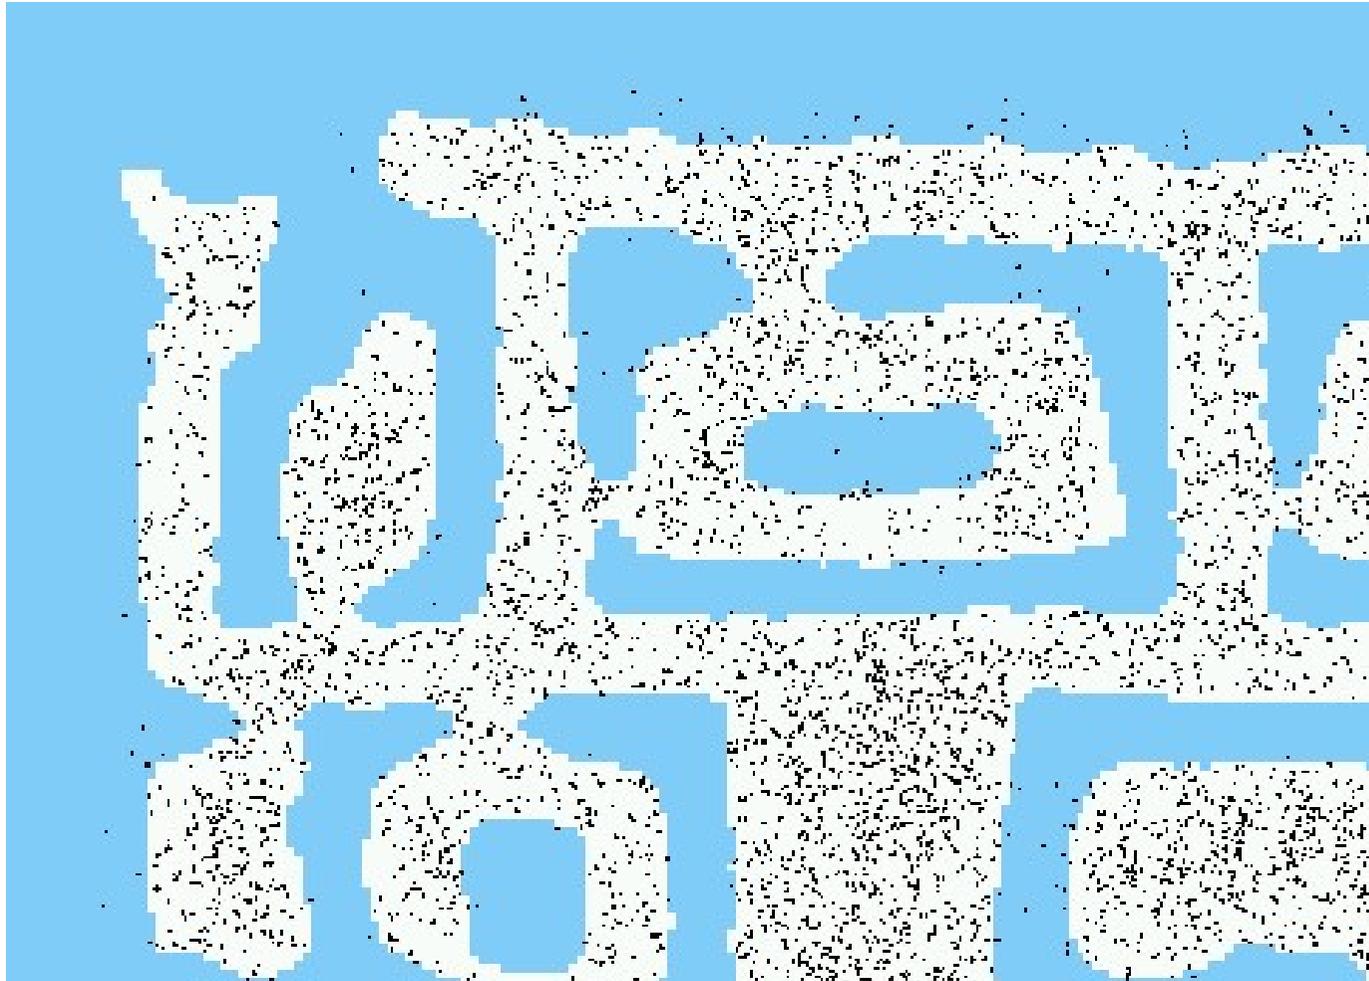

Sample-based Localization (sonar)

Initial Distribution

Global Localization Using Vision

Vision-based Localization

Limitations

- The approach described so far is able
 - to track the pose of a mobile robot and
 - to globally localize the robot
- How can we deal with localization errors (i.e., the kidnapped robot problem)?

Approaches

- Randomly insert a fixed number of samples with randomly chosen poses
- This corresponds to the assumption that the robot can be teleported at any point in time to an arbitrary location
- Alternatively, insert such samples inverse proportional to the average likelihood of the observations (the lower this likelihood the higher the probability that the current estimate is wrong).

Summary – Particle Filters

- Particle filters are an implementation of recursive Bayesian filtering
- They represent the posterior by a set of weighted samples
- They can model arbitrary and thus also non-Gaussian distributions
- Proposal to draw new samples
- Weights are computed to account for the difference between the proposal and the target
- Monte Carlo filter, Survival of the fittest, Condensation, Bootstrap filter

Summary – PF Localization

- In the context of localization, the particles are propagated according to the motion model.
- They are then weighted according to the likelihood model (likelihood of the observations).
- In a re-sampling step, new particles are drawn with a probability proportional to the likelihood of the observation.
- This leads to one of the most popular approaches to mobile robot localization
